Re: Remedial Investigation Report- NRU- Radford Army Ammunition Plant

Dear Mr. McKenna:

The Virginia Department of Environmental Quality (VDEQ) has reviewed the Final Remedial Investigation Report dated June 2010 for the New River Unit (RAAP-044) at Radford Army Ammunition Plant and approves the report as revised.

Please contact me at (804) 698-4498 if you have any questions or comments regarding the above site.

J L Cutler Jr

Final Remedial Investigation Report, New River Unit (RAAP-044) BDDT, BLA, IAA, RY, WBG, and Groundwater, Volumes I and II, June 2010

Dear Mr. Cutler:

This letter is to acknowledge transmittal of the subject document that was sent to you on July7, 2010. Enclosed is a copy of the 7 July 2010 transmittal email.

Please coordinate with and provide any questions or comments to myself at (540) 639-8658, Jerry Redder ATK staff (540) 639-7536 or Jim McKenna, ACO Staff (540) 731-5782.

Sincerely,

P.W. Holt, Environmental Manager
Alliant Techsystems Inc.

All,

The subject report for the NRU will be sent out today by ARCADIS to the POCs listed below with the Fed Ex tracking numbers. This report was revised per the attached response to comments.

Name:	Copies	Tracking Number
Mr. James McKenna	2 Copies and 2CDs	7988 2589 1445
Mr. Richard Mendoza	1 Copy and 1 CD	7937 0294 0956
Ms. Susan Ryan	1 CD	7937 0296 9223
Mr. Tom Meyer	1 Copy and 1CD	7988 2593 9899
Mr. Dennis Druck	1 Copy	7937 0298 8630
Mr. James Cutler	1 Copy	7937 0299 3743
Ms. Karen Sismour	1 Copy	7937 0300 2111
Ms. Elizabeth Lohman	1 CD	7937 0307 2714

Jim Cutler, from our June 2, 2010 conference call and our June 17, 2010 site visit, we anticipate DEQ concurrence on the RI report, therefore it would be helpful if we could obtain DEQ concurrence on or about July 23, 2010. As a reminder we also need to get DEQ comments on the draft FS.

Thank you all for your support of the Radford AAP Installation Restoration Program.

Comments and Responses on the
Draft RI Report
New River Unit RFAAP 044
Radford Army Ammunition Plant
April 2010

Item No.	Report Reference	COMMENT	RESPONSE
Commenter: Ahmet Bulbulkaya (VDEQ) – HHRA Comments. Memo to Jim Cutler dated March 5, 2010			
1	Appendix A: Page 2-2, Section 2.1.1:	The criteria employed to determine whether a groundwater sample result was suitable for the risk assessment data set greatly reduced the inorganic groundwater data set available for the risk assessment. After turbidity was considered, with inorganic results rejected when turbidity was high, the inorganic groundwater data available to the risk assessment was reduced to just one round. Another round of inorganic groundwater data is recommended for all Study Areas of the site.	*Agreed. Use of dissolved sample results when turbidity levels are high is consistent with guidance provided by EPA for sites at Radford. In addition, ARCADIS collected another round of groundwater samples at RFAAP-NRU on April 6 and 7, 2010. Consistent with the 2009 sampling event, all eleven groundwater monitoring wells at the facility and four spring locations were sampled during this event. At the request of VDEQ (email from Jim Cutler to Jim McKenna dated March 25, 2010) as further clarified in a 30 April 2010 telecommunication between VDEQ (Cutler) and ARCADIS (Wisbeck), all of the groundwater samples were analyzed for VOCs, metals, PAHs, PCBs, and explosives. The three monitoring wells at the Western Burning Ground area and the two monitoring wells located at the Northern Burning Ground were also analyzed for dioxins/furans. The analytical data from this sampling event will be incorporated into the Final RI Report.*

Item No.	Report Reference	COMMENT	RESPONSE
2	Appendix A: Page 2-3, Section 2.2	The most currently accepted method of assessing carcinogenic risk for mutagens is never discussed this section and was not used in the risk assessment. This is evidenced by the fact that the carcinogenic risk equations for mutagens are not included in the risk assessment tables that present the carcinogenic risk algorithms beginning with Table A.2-11. The effect of not using the most current USEPA recommended methodology for assessing mutgenic risk is that carcinogenic risk is underestimated to residential receptors potentially exposed to mutagens (many of the PAHs). Therefore carcinogenic residential risk totals should be revised for Study Areas that have significant levels of PAHs.	*Agreed. The human-health risk assessments (HHRA) for the sites within the New River Unit have been revised so that the residential scenarios utilize the early-life adjustment for assessing carcinogenic risk associated with mutagens. This methodology is consistent with the USEPA's Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens.* *The inclusion of this guidance resulted in a change in the conclusions and recommendations for the BDDT area. Potential risks for the residential receptor calculated using the Supplemental Guidance are greater than the USEPA's acceptable risk range of 1E-4 to 1E-6. Therefore evaluation of the response action alternatives available for the BDDT area will be presented in the FS. There were no changes to the conclusions and recommendations for any of the other Study Areas at RFAAP-NRU.*

Comments and Responses on the
Draft RI Report
New River Unit RFAAP 044
Radford Army Ammunition Plant
April 2010

Item No.	Report Reference	COMMENT	RESPONSE
3	Appendix A: Page 2-6, Section 2.2.1.1, last sentence:	This sentence states that "Constituents selected as COPCs based on the protection of leaching to groundwater were evaluated through the site-wide groundwater assessment." It is not clear that COPCs were selected based on leaching to groundwater. It states in an earlier paragraph of this section that the residential and industrial RSLs were used to screen COPCs but does not mention the "Protection of Groundwater Soil Screening Levels" contained in the RSL table.	*Agreed. The HHRA has been revised to indicate more clearly that the selection of COPCs in groundwater was based on concentrations actually measured in groundwater, not using soil criteria developed for protection of groundwater.*
4	Appendix A: Page 2-14, Section 2.2.3.3.1 (and Table A.2-10):	This page (and the table) presents exposure factors for the "Site Worker". More information should be provided in the narration as to the type of worker that is being considered. Section 2.2.3.1 describes the potential current receptor as being a site commercial/industrial worker yet Section 2.2.3.3.1 also mentions cutting grass. It is also unclear how a wading scenario fits in with a typical commercial/industrial worker exposure scenario. If a landscaper type of exposure is envisioned the soil ingestion rate of 50 mg/kg is too low. A more appropriate can be obtained from the RSL table which uses 100 mg/day for its "composite worker" scenario that is used to develop default industrial soil screening values, and that is also intended to capture exposure from landscaping activities.	*The "Site Worker" is not classified as a landscaper. The Site Worker is someone who conducts maintenance or mowing activities at the Site. That person is expected to work only above ground. Very little soil contact is envisioned as none of his or her responsibilities would involve digging or planting. ARCADIS believes that the 50 mg/day soil ingestion rate would be adequately conservative for this receptor. However, to comply with VDEQ's request ARCADIS changed the soil ingestion rate from 50 mg/kg to 100 mg/kg to match the value recommended for the "composite worker" within the RSL tables. This change did not result in any changes to the conclusions or recommendations for any of the Study Areas at RFAAP-NRU.*

Item No.	Report Reference	COMMENT	RESPONSE
5	Appendix A: Page 2-15, Section 2.2.3.3.2 (and Table A.2-10):	The exposure duration for an adult hypothetical future resident should be 24 years instead of 30 years. Adult carcinogenic risk resulting from 24 years of exposure should be added to the child carcinogenic risk from 6 years of exposure so that a resident carcinogenic risk for a total of 30 years results. Note that mutagens have their own life-stage specific algorithms that incorporate 4 life stages beginning at birth and ending at 30 years.	*Agreed. The exposure durations have been adjusted for the hypothetical future resident risk calculations.* *Please see Response to Comment No. 2..*
6	Appendix A: Page 2-16, Section 2.2.3.3.3:	What was the basis or rationale behind the statement that, *"Construction workers are not likely to come into contact with shallow groundwater during a hypothetical construction project, since the depth to shallow groundwater is at least 10 feet."* Was there any research to support the claim that trenches are not expected go deeper than 10 feet.	*Groundwater at RFAAP is generally encountered in the karst bedrock underlying the site. As indicated in Table 3-1 depth to groundwater was greater than 120 ft bgs at the BLA; greater than 30 ft at the IAA; greater than 90 ft at the NBG; and greater than 12 ft at the WBG. Standard trenching techniques would not be useful for cutting into bedrock; therefore, it is highly unlikely that construction workers would come into contact with groundwater within the bedrock. Furthermore, no reasonably foreseeable trenching activities (i.e., utility line trenches) would be expected to extend below 10 ft or within groundwater.*
7	Appendix A: Page 2-19, Section 2.2.4.3:	For the Study Areas where lead was a COPC the IEUBK results are presented without documentation. Please provide supporting information and documentation for the IEUBK model runs for these Study Areas.	*Agreed. The HHRA has been revised to include the complete documentation for the IEUBK model runs.*

Comments and Responses on the
Draft RI Report
New River Unit RFAAP 044
Radford Army Ammunition Plant
April 2010

Item No.	Report Reference	COMMENT	RESPONSE
8	Appendix A: Page 3-2, Section 3.3:	It is agreed that the sampling data from the riprap covered portion of the BDDT can be treated differently than other areas of the BDDT Study Area. However the usefulness of the statistical comparison between the riprap dataset to the remaining larger BDDT dataset is unclear. A more direct approach is to determine the risk associated with the riprap area data separately from the remaining BDDT area.	*Agreed. The HHRA has been revised to evaluate soil beneath the riprap both concurrently with soil (site-wide) in the remainder of the ditch and separately. This approach allows for the evaluation of potential health risks should the riprap be removed and the need for long-term controls on the site.*
9	Appendix A: Page 3-9, Section 3.4.5 and included table:	In this section it is reported that carcinogenic risk to the hypothetical future child resident at the BDDT from combined surface and subsurface soil is 1E-04 and therefore acceptable. Note that if carcinogenic risk was calculated for a combined adult/child resident using the mutagen equations discussed above the residential carcinogenic risk would be significantly greater than 1E-04.	*Agreed, with additional clarification. The HHRA was revised to include procedures requested in this and in Comment Nos. 2, 5, and 8.* *Please see Response to Comment No. 2.-NRU.*
10	Appendix A: Page 4-9, Section 4.4.4.3:	Since PAHs are driving the unacceptable hypothetical future residential risk at the BLA Study Area it is expected to be even higher when the above comment is taken into account.	*Agreed. However, this did not change the conclusions/recommendations for the BLA Study Area because potential residential risks were already greater than EPA's generally acceptable risk range and the Feasibility Study evaluated remedial alternatives for the BLA under a future residential land-use scenario. Therefore, no additional revisions to the conclusions of the RI or the Feasibility Study were required.*

Item No.	Report Reference	COMMENT	RESPONSE
11	Appendix A: Page 4-10:	More documentation of the IEUBK modeling runs should be provided. The cited table (Table A.4.HHRA-18) only provides the predicted range of blood lead levels. There should be more information on model inputs provided. This comment applies to the other study areas where lead was COPC (i.e, the IAA and WBG).	*Agreed. The HHRA has been revised to include the complete documentation for the IEUBK model runs.*

Comments and Responses on the
Draft RI Report
New River Unit RFAAP 044
Radford Army Ammunition Plant
April 2010

Item No.	Report Reference	COMMENT	RESPONSE
12	Appendix A: Page 6-10, Section 6.4.5:	Please provide more information regarding the detection of PCP of 830 mg/kg, which is the driver for the unacceptable residential carcinogenic risk reported in this section. How extensive was the follow up investigation and attempts to duplicate the elevated hit?	*Pentachlorophenol (PCP) was detected at a concentration greater than the industrial RSL (9 mg/kg) in one surface soil sample [TR-02C (830 mg/kg)] which was collected in 1998 at a former pole-mounted transformer location. The concentration of PCP in a duplicate surface soil sample collected at this location (TR-02A) was only 0.11mg/kg.* *A total of 33 soil samples (20 surface soil samples and 13 subsurface soil samples) collected during subsequent investigations at the Rail Yard were analyzed for PCP. PCP was not detected in any of these samples, nor was PCP detected in any surface water or sediment samples at the Rail Yard.* *As PCP is known to have been used as a wood preservative for utility poles, the single elevated detection of PCP at sample location TR-02C has been linked to the former utility pole at this sample location. The fact that PCP was not detected at elevated levels in the duplicate sample at this location or in any other soil samples at the site indicates that the elevated detection was limited to the area in the immediate vicinity of the utility pole.*

Radford Army Ammunition Plant
April 2010

Item No.	Report Reference	COMMENT	RESPONSE
13	Appendix A: Page 7-8, Section 7.4.1.5 and Table A.7.HHRA-5.	How was it determined that the fish tissue sampling would be limited to only the metals listed on the table?	*The table summarizes constituents that were detected in the fish samples and does not present the complete analyte list. A total of 16 fish tissue samples were collected from the Western Burning Ground pond. The samples were analyzed for TCL PCBs and TAL metals (see Table 9-16 of main RI Report for full-list of constituents included in the analyses). No PCBs were detected in any of the samples, nor was lead. Table A.7.HHRA-5 only lists the inorganic constituents that were detected in the samples.*
Commenter: James Cutler (VDEQ) – NRU RI Comments. Email to Jim McKenna dated March 17, 2010			
14		The soils at the BDDT appear to be adequately delineated. The level of PAH contamination in the sediments has fluctuated over time. Depending on the resolution of the HHRA comments additional sediment samples may be required to demonstrate that there is no significant continued release to the stream.	*The revised HHRA indicates potential risks greater than EPA's generally acceptable risk range for the future residential receptor. There are no unacceptable risks associated with exposure to sediment at the site. Continued impacts to the stream downgradient of the BDDT area are not expected because 1) the source area has been removed, and 2) the area downgradient of the rip rap is now heavily vegetated with grasses and the slope is fairly gentle so continued erosion of impacted soil into the stream is unlikely.*
15		Section 6.4.6.4 it is stated that 4 samples were collected around BLASB02. The text states that PAHs were detected above screening levels but this information is not indicated on Figure 6-8.	*Figure 6-8 has been corrected to display the PAH detections at sample locations BLA-SS005, BLA-SS006, BLA-SS007, and BLA-SS008. These are the sample locations that were collected around BLASB02.*

Item No.	Report Reference	COMMENT	RESPONSE
16		The further delineation of PAHs at the BLA is problematic since no specific source has been identified. Depending on the resolution of the HHRA comments additional delineation may be required.	*The revisions to the HHRA requested in Comments No. 2, 8, and 9 did not change the conclusion of the HHRA which identified PAHs as risk drivers under a hypothetical future residential land-use scenario. PAHs do not present unacceptable risks to the industrial site worker or construction worker under the current military/industrial land-use scenario. Therefore, no additional characterization and no revisions to the Feasibility Study for RFAAP-NRU are required.*
17		On page 7-32 and 7-56 it is stated that no explosives were found above RSLs in the building areas. Is this consistent with the fact that the primary risk driver in soil is 2,4-DNT?	*The text on pages 7-32 and 7-56 were revised to discuss that 2,4-dinitrotoluene (DNT) was detected in two samples from a single boring collected during the initial 1997 site investigation. This constituent was not detected during any of the subsequent investigations at the site, including samples collected near the location of the original detection. The HHRA identified 2,4-DNT as a risk driver; however, a response action is not recommended for this constituent due to the extremely limited distribution.*

Comments and Responses on the
Draft RI Report
New River Unit RFAAP 044
Radford Army Ammunition Plant
April 2010

Item No.	Report Reference	COMMENT	RESPONSE
18		PCB's appear more prevalent at the IAA than the BLA. On page 7-12 it is reported that Aroclor 1254 was detected above industrial RSLs around buildings 504, 509, 522 and 529. On page 7-55 (last paragraph) it is stated that screening levels were exceeded adjacent to buildings 502, 504, 8101, 8102-5 and 8102-A. Were all samples included on Figure 7-8?	*Figure 7-8 does not present the results for the conductive flooring samples because the locations are unknown. The results discussed in Section 7.4.5 on page 7-12 are for samples of the conductive flooring material, that were collected from Buildings 502, 504, 509, 522, and 529 during the USACE's 2002 Conductive Flooring Assessment. Figure 7-8 only displays the results of soil samples that were collected in the southern portion of the IAA around Buildings 502, 504, 522, and 529; as well as the other Buildings in this area. The results for the Soil samples collected around Buildings 8101, 8201-5 and 8102-A are shown on Figure 7-7.*
19		Figure 9-9. Industrial exceedances should be noted.	*Agreed. Figure 9-9 has been updated to indicate concentrations that are greater than the industrial RSLs.*
20		On page 9-50 it is stated that lead was detected above tap water RSLs in 4 water samples. These samples are not indicated on Figure 9-11.	*Agreed. Figure 9-11 has been updated to show the sample locations where concentrations were greater than the RSLs.*
21		Based on the low level detections in groundwater the conceptual model presented appears to be adequate for the site area. It is recommended that an additional round of sampling be conducted to resolve any discrepancies between the previous two rounds.	*Agreed. See Response to Comment No. 1.*

Subject: NRU RAAP 44 - Response to VDEQ Comments on the Ecological Risk Assessment (UNCLASSIFIED)
Attachments: RAAP44_ERA RTC_VDEQ 2010 05 20 (3).pdf

Importance: High

Classification: UNCLASSIFIED
Caveats: FOUO

Jim C.,

Attached are the RFAAP responses to the May 5, 2010 VDEQ comments on the Ecological Risk Assessment (ERA) for RAAP-044 (New River Unit).
With these responses, all comments RFAAP has received on the Remedial Investigation (RI) Report have been addressed. (Note on April 30, 2010 RFAAP responded to DEQ comments [March 5 and 17, 2010] on the HHRA and RI Report.)

It is not anticipated that in addressing these comments there will be any required revisions to the conclusions and recommendations for the RI Report. Also, there are no anticipated revisions to the Feasibility Study (FS) Report resulting from VDEQ comments on the RI, HHRA, or ERA.

We spoke earlier about maybe meeting and going over these comments. If after reviewing our responses you still think we need to meet and discuss, I would strongly recommend the morning of Thursday, June 17, 2010 at 1000am as RFAAP and ARCADIS will be conducting a RAB site tour of the NRU later that same day. In this way we would have the opportunity to visit the NRU before the RAB tour to help clarify any remaining items.

Thanks,
Jim M.

Commenter: Ahmet Bulbulkaya and Jim Cutler (VDEQ) – Eco Comments. Email dated May 5, 2010			
1	Appendix A – General Ecological Risk Assessment	Use of Background: During the refinement step of the BERA the COPECs that were determined through the SLERA were examined to determine if they warranted being carried through the remaining steps of the USEPA eight-step ecological risk assessment process. For inorganics in surface soil this often involved comparing EPCs to site background concentrations as reported in the 2001 IT Facility-Wide Background Study Report ("Background Study"). Sometimes this involved employing the range of background concentrations for a particular inorganic constituent and sometimes the reported point estimate was used. Note that the point estimate background concentration was used in the SLERA initial screening steps. Although this type of background comparison occurred earlier in the eight-step process than is typically called for by the USEPA this seemed to be an appropriate background screen and use of the Background Study. However, use of the range of background samples to define the extent of potential negative ecological impacts seemed to be an inappropriate and unintended use of the Background Study. In the conclusions of the Background Study it is stated that "The final set of point estimates for the background data set, therefore, are based on calculated 95% UTLs for a single facility-wide data set that represents surface and subsurface soil from the MMA and the NRU areas. These values are included as a point of reference for point-by-point comparisons for site screening." If background ranges from the Background Study are to be considered for the refinement of COPECs the dataset from the NRU should be segregated from the MMA dataset. Otherwise, only the 95% UTLs should be used for COPEC refinement. During the refinement of sediment COPECs inorganic sediment concentrations were sometimes compared to soil background values from the Background Study. In this case sediment concentrations should not be compared to soil background levels at all. To determine background sediment concentrations background sediment samples should be collected. If this is not practicable then sediment inorganic COPEC refinement based on background should not occur.	*Agreed. Although the use of the background data as part of the SLERA screening process was discussed with VDEQ representatives during the June 28, 2008 site visit, this level of detail was not discussed. As requested, the document has been modified to use only the point estimate (UTL) from the Background Study for screening soils as opposed to the range of background concentrations.* *In addition, in the absence of background data specific to sediment, that refinement step has been removed from the COPEC selection process for sediments. The majority of the sediment COPECs affected by this modification do not have sediment ecological screening levels (ESLs), therefore the final risk estimates are not significantly impacted. A discussion has been added to the uncertainty section.*

New River Unit RFAAP 044
Radford Army Ammunition Plant
May 2010

Item No.	Report Reference	COMMENT	RESPONSE
2	Appendix A – General Ecological Risk Assessment	Bioaccumulation modeling: Bioaccumulation modeling was performed only on the constituents remaining after the BERA screening. By initiating the modeling after this step, and not after the initial SLERA screening, there is the potential for prematurely eliminating constituents that have a bioaccumulative potential from the eight-step process. Bioaccumulative constituents remaining after the initial SLERA screening steps should have been run through the terrestrial and aquatic food chain models.	*Agreed. The approach used for selection of constituents for consideration in the food web modeling was consistent with the approach used at other military installations, and is believed to effectively capture the significant bioaccumulative constituents for food chain modeling.* *However, in accordance with the RFAAP SLERA approach (Final Process for Ecological Risk Assessment-Radford AAP- September 17, 2007 revision), all bioaccumulative constituents detected in sediments and soil will be retained and evaluated in the food web modeling, regardless of the outcome of the SLERA toxicity screening. It is not anticipated that the inclusion of constituents detected at levels less than screening levels will change the overall conclusions and recommendations of the ERA because of either the low concentrations and/or infrequent detections of these compounds.*
3	Page 2-27, Section 2.3.1.1.4	Dioxins and Furans: There was no description of potential effects of these compounds as there was for the other constituent classes listed in this section. Please add a brief description.	*Agreed. A description of the potential effects associated with dioxins and furans has been added to Section 2.3.1.1.4.*

Comments and Responses on the
Draft RI Report
(Ecological Risk Assessment Component)
New River Unit RFAAP 044

May 2010

Item No.	Report Reference	COMMENT	RESPONSE
4	Page 3-2, Section 3.3	It is agreed that the sampling data from the riprap covered portion of the BDDT can be treated differently than other areas of the BDDT Study Area. However the usefulness of the statistical comparison between the riprap dataset to the remaining larger BDDT dataset is unclear. A more direct approach would be to determine the ecological risk associated with the riprap area data separately from the remaining BDDT area.	*Agreed. The risk assessment has been revised to evaluate soil beneath the riprap both concurrently with soil (site-wide) in the remainder of the ditch and separately. This approach allows for the evaluation of potential ecological risks should the riprap be removed and the need for long-term controls on the site.* *The results of the revised evaluation indicate that no further evaluation of ecological risks is warranted and there is no need for long-term controls at the site. Note this revision did not change the conclusion, thus no revision to the recommendations were made.*
5	Page 7-14, Section 7.5:	It is unclear what ecological risk assessment guidance from Virginia is being referred to in this and other sections of the risk assessment. Please clarify.	*Agreed. The State of Virginia has not developed an ERA guidance document. Therefore, the reference to Virginia ecological risk assessment guidance in Section 7.5, and in other sections of the report, will be removed in the revised ERA report.* *The sentence has been changed to read as follows:* *"The ERA was conducted in a manner consistent with USEPA guidance for ecological risk assessment (USEPA 2001a; 2000b; 1997c)."*
6	Page 7-24:	The reference for the background level of antimony in Virginia is unfamiliar to this office. Please discuss and elaborate on its applicability to the NRU.	*Agreed. The cited reference of USEPA (1995) is incorrect; the correct reference is USEPA (2005b). The background antimony level of 1.2 mg/kg is the mean concentration reported in surface soil in the State of Virginia, and can be found in Table 2.3 of USEPA (2005b).*

Item No.	**Report Reference**	**COMMENT**	**RESPONSE**
7	Page 7-25, bottom of page:	For the food chain analysis of the shrew and robin the bioaccumulative COPECS should have been selected from the 20 COPECs determined from the SLERA. In the case of the Western Burning Ground this means that arsenic, cadmium and selenium should have been included in the terrestrial food chain modeling.	*Agreed. As discussed in the response to General Comment No. 2, the approach used for selection of constituents for consideration in the food web modeling is believed to effectively capture the significant bioaccumulative constituents for food chain modeling.* *However, in accordance with the RFAAP SLERA approach (Final Process for Ecological Risk Assessment-Radford AAP- September 17, 2007 revision), all bioaccumulative constituents detected in sediments and soil will be retained and evaluated in the food web modeling, regardless of the outcome of the SLERA toxicity screening. It is not anticipated that the inclusion of constituents detected at levels less than screening levels will change the overall conclusions and recommendations of the ERA because of either the low concentrations and/or infrequent detections of these compounds.*

Item No.	Report Reference	COMMENT	RESPONSE
8	Page 7-36, Aquatic Food Chain Model:	There is not enough information to assume that adverse population effects are not occurring at the pond. The extremely elevated hazard quotients for lead and zinc for mink, and to a lesser degree, the elevated hazard quotients for zinc for the great blue heron, warrant additional analysis. The rationale or intent of the discussion in the last paragraph on Page 7-36 that describes excluding the maximum detect of lead and zinc is unclear. Is the intent to suggest that the highest concentration detected in the sediments will be removed in a remedial action? A data gap in the foodchain analysis is that lead was not analyzed for in fish. This data gap should be filled by additional fish sampling.	*The HQs calculated for the refined scenario were based on:* • *measured concentrations in fish tissue for those COPCs that were analyzed (e.g., lead which was analyzed but not detected in any fish tissue samples),* • *modeled concentrations in fish tissue for COPCs other than those analyzed (e.g., PAHs), and* • *modeled concentrations for other dietary items (e.g., vegetation and invertebrates).* *The modeled concentrations were based on the use of soil BAFs which in some cases predicted tissue concentrations greater than 100 percent. These overestimated tissue concentrations are falsely elevating the refined HQs. Therefore, the dose modeling and related BAFs will be revisited.* *Based on this information it is anticipated that the refined HQs will be lower, thus supporting the conclusion that the small and localized area of elevated COPC concentrations in sediment is unlikely to result in a significant exposure to ecological receptors.*

New River Unit RFAAP 044
Radford Army Ammunition Plant
May 2010

Item No.	Report Reference	COMMENT	RESPONSE
9	Page 7-37	Please provide more information as to the main component of the diet that is driving the elevated hazard quotients for the mink and the great blue heron. Add discussion as to why the hazard quotients went up so markedly in the refined scenario food chain modeling as compared to the maximum scenario modeling run. If the elevated hazard quotients for lead and zinc are being driven by fish consumption then it would not be appropriate to focus exclusively on the limited area of elevated sediment impacts surrounding WBGSW/SD10 as the only significantly impacted ecological habitat. If fish consumption is driving the risk then the areal extent of the whole pond would be considered impacted habitat. Note that the unnamed pond is estimated at 3.6 acres in size which would surpass the de minimis size criteria described on page 2-32. This would lead to the conclusion that, if fish consumption by the mink and great blue heron is driving the elevated hazard quotients found in Table A.7.ERA-13 and Table A.7.ERA-15 then population effects are possible and that the ecological risk assessment process should continue into the remaining steps of the USEPA eight-step process.	*The refined scenario incorporated consideration of additional dietary items in the dose modeling for aquatic species However, many of these modeled concentrations were based on the use of soil BAFs, resulting in overestimated tissue concentrations. Upon further consideration, use of these overly conservative dietary estimates seems inappropriate, particularly given the actual measured concentrations in fish tissue. Assuming that consumption of fish is the primary exposure route for piscivorous species such as the mink and great blue heron, actual exposures would be much less than estimated in the refined scenario using the overestimated tissue concentrations for other dietary components. Based on these considerations, the dose modeling has been revised to more accurately reflect actual exposures to these species.*

Subject: NRU- Eco risk comments

Jim,

The following are Ahmet's comments regarding his review of the ecological risk assessment sections of Appendix A - Risk Assessment to the Draft Remedial Investigation report for the New River Unit
(RAAP-044):

General comments:

1. Use of Background: During the refinement step of the BERA the COPECs that were determined through the SLERA were examined to determine if they warranted being carried through the remaining steps of the USEPA eight-step ecological risk assessment process. For inorganics in surface soil this often involved comparing EPCs to site background concentrations as reported in the 2001 IT Facility-Wide Background Study Report ("Background Study"). Sometimes this involved employing the range of background concentrations for a particular inorganic constituent and sometimes the reported point estimate was used. Note that the point estimate background concentration was used in the SLERA initial screening steps. Although this type of background comparison occurred earlier in the eight-step process than is typically called for by the USEPA this seemed to be an appropriate background screen and use of the Background Study. However, use of the range of background samples to define the extent of potential negative ecological impacts seemed to be an inappropriate and unintended use of the Background Study.

In the conclusions of the Background Study it is stated that "The final set of point estimates for the background data set, therefore, are based on calculated 95% UTLs for a single facility-wide data set that represents surface and subsurface soil from the MMA and the NRU areas. Theses values are included as a point of reference for point-by-point comparisons for site screening."

If background ranges from the Background Study are to be considered for the refinement of COPECs the dataset from the NRU should be segregated from the MMA dataset. Otherwise, only the 95% UTLs should be used for COPEC refinement.

During the refinement of sediment COPECs inorganic sediment concentrations were sometimes compared to soil background values from the Background Study. In this case sediment concentrations should not be compared to soil background levels at all. To determine background sediment concentrations background sediment samples should be collected. If this is not practicable then sediment inorganic COPEC refinement based on background should not occur.

2. Bioaccumulation modeling: Bioaccumulation modeling was performed only on the constituents remaining after the BERA screening. By initiating the modeling after this step, and not after the initial SLERA screening, there is the potential for prematurely eliminating constituents that have a bioaccumulative potential from the eight-step process. Bioaccumulative constituents remaining after the initial SLERA screening steps should have been run through the terrestrial and aquatic food chain models.

Specific Comments:

3. Page 2-27, Section 2.3.1.1.4, Dioxins and Furans: There was no description of potential effects of these compounds as there was for the other constituent classes listed in this section. Please add a brief description.

4. Page 3-2, Section 3.3: It is agreed that the sampling data from the riprap covered portion of the BDDT can be treated differently than other areas of the BDDT Study Area. However the usefulness of the statistical comparison between the riprap dataset to the remaining larger BDDT dataset is unclear. A more direct approach would be to determine the ecological risk associated with the riprap area data separately from the remaining BDDT area.

5. Page 7-14, Section 7.5: It is unclear what ecological risk assessment guidance from Virginia is being referred to in this and other sections of the risk assessment. Please clarify.

6. Page 7-24: The reference for the background level of antimony in Virginia is unfamiliar to this office. Please discuss and elaborate on its applicability to the NRU.

7. Page 7-25, bottom of page: For the food chain analysis of the shrew and robin the bioaccumulative COPECS should have been selected from the 20 COPECs determined from the SLERA. In the case of the Western Burning Ground this means that arsenic, cadmium and selenium should have been included in the terrestrial food chain modeling.

8. Page 7-36, Aquatic Food Chain Model: There is not enough information to assume that adverse population effects are not occurring at the pond. The extremely elevated hazard quotients for lead and zinc for mink, and to a lesser degree, the elevated hazard quotients for zinc for the great blue heron, warrant additional analysis. The rationale or intent of the discussion in the last paragraph on Page 7-36 that describes excluding the maximum detect of lead and zinc is unclear. Is the intent to suggest that the highest concentration detected in the sediments will be removed in a remedial action? A data gap in the foodchain analysis is that lead was not analyzed for in fish. This data gap should be filled by additional fish sampling.

9. Page 7-37: Please provide more information as to the main component of the diet that is driving the elevated hazard quotients for the mink and the great blue heron. Add discussion as to why the hazard quotients went up so markedly in the refined scenario food chain modeling as compared to the maximum scenario modeling run. If the elevated hazard quotients for lead and zinc are being driven by fish consumption then it would not be appropriate to focus exclusively on the limited area of elevated sediment impacts surrounding WBGSW/SD10 as the only significantly impacted ecological habitat. If fish consumption is driving the risk then the areal extent of the whole pond would be considered impacted habitat. Note that the unnamed pond is estimated at 3.6 acres in size which would surpass the de minimus size criteria described on page 2-32. This would lead to the conclusion that, if fish consumption by the mink and great blue heron is driving the elevated hazard quotients found in Table A.7.ERA-13 and Table A.7.ERA-15 then population effects are possible and that the ecological risk assessment process should continue into the

remaining steps of the USEPA eight-step process.

Subject: NRU RI comments

Jim,

The following are VDEQ's comments on the RI in addition to the HHRA comments previously submitted.

In general after multiple investigations the NRU appears to be sufficiently characterized to formulate remedial options. Any additional delineation may depend on proposed removal actions and can most likely be addressed by confirmation samples.

1. The soils at the BDDT appear to be adequately delineated. The level of PAH contamination in the sediments has fluctuated over time.
Depending on the resolution of the HHRA comments additional sediment samples may be required to demonstrate that there is no significant continued release to the stream.

2. In Section 6.4.6.4 it is stated that 4 samples were collected around BLASB02. The text states that PAHs were detected above screening levels but this information is not indicated on Figure 6-8.

3. The further delineation of PAHs at the BLA is problematic since no specific source has been indentified. Depending on the resolution of the HHRA comments additional delineation may be required.

4. On page 7-32 and 7-56 it is stated that no explosives were found above RSLs in the building areas. Is this consistent with the fact that the primary risk driver in soil is 2,4-DNT?

5. PCB's appear more prevalent at the IAA than the BLA. On page 7-12 it is reported that Aroclor 1254 was detected above industrial RSLs around buildings 504, 509, 522 and 529. On page 7-55 (last paragraph) it is stated that screening levels were exceeded adjacent to buildings 502, 504, 8101, 8102-5 and 8102-A. Were all samples included on Figure 7-8?

6. Figure 9-9. Industrial exceedances should be noted.

7. On page 9-50 it is stated that lead was detected above tap water RSLs in 4 water samples. These samples are not indicated on Figure 9-11.

8. Based on the low level detections in groundwater the conceptual model presented appears to be adequate for the site area. It is recommended that an additional round of sampling be conducted to resolve any discrepancies between the previous two rounds.

Please contact me with any comments or questions regarding the above comments.
I will forward FS comments shortly.

Thanks,

Jim

DIVISION OF WASTE PROGRAM COORDINATION

OFFICE OF REMEDIATION PROGRAMS

MEMORANDUM

TO: Jim Cutler

CC: Karen Sismour, Pat McMurray

FROM: Ahmet Bulbulkaya

DATE: March 5, 2010

SUBJECT: Human Health Risk Assessment (Appendix A) submitted as part of the Remedial Investigation for the New River Unit (NRU)

My comments on the subject document are below. Note that comments on the Ecological Risk Assessment and Feasibility Study are forthcoming.

1. Page 2-2, Section 2.1.1: The criteria employed to determine whether a groundwater sample result was suitable for the risk assessment data set greatly reduced the inorganic groundwater data set available for the risk assessment. After turbidity was considered, with inorganic results rejected when turbidity was high, the inorganic groundwater data available to the risk assessment was reduced to just one round. Another round of inorganic groundwater data is recommended for all Study Areas of the site.

2. Page 2-3, Section 2.2: The most currently accepted method of assessing carcinogenic risk for mutagens is never discussed this section and was not used in the risk assessment. This is evidenced by the fact that the carcinogenic risk equations for mutagens are not included in the risk assessment tables that present the carcinogenic risk algorithms beginning with Table A.2-11. The effect of not using the most current USEPA recommended methodology for assessing mutgenic risk is that carcinogenic risk is underestimated to residential receptors potentially exposed to mutagens (many of the PAHs). Therefore carcinogenic residential risk totals should be revised for Study Areas that have significant levels of PAHs.

   For additional information this concept is discussed in the supporting information for the current USEPA Regional Screening Level (RSL) Table. The explanation included in Section 5.14 of the RSL User's Guide states that:

   "Some of the cancer causing analytes in this tool operate by a mutagenic mode of action for carcinogenesis. There is reason to surmise that some chemicals with a mutagenic mode of action, which would be expected to cause irreversible changes to DNA, would exhibit a

greater effect in early-life versus later-life exposure. Cancer risk to children in the context of the U.S. Environmental Protection Agency's cancer guidelines (U.S. EPA, 2005) includes both early-life exposures that may result in the occurrence of cancer during childhood and early-life exposures that may contribute to cancers later in life. In keeping with this guidance, separate cancer risk equations are presented for mutagens. The mutagen vinyl chloride has a unique set of equations. Consult Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens, EPA/630/R-03/003F, March 2005 for further information. http://www.epa.gov/oswer/riskassessment/sghandbook/chemicals.htm provides more detailed information about what chemicals are considered mutagens."

3. Page 2-6, Section 2.2.1.1, last sentence: This sentence states that "Constituents selected as COPCs based on the protection of leaching to groundwater were evaluated through the site-wide groundwater assessment." It is not clear that COPCs were selected based on leaching to groundwater. It states in an earlier paragraph of this section that the residential and industrial RSLs were used to screen COPCs but does not mention the "Protection of Groundwater Soil Screening Levels" contained in the RSL table.

4. Page 2-14, Section 2.2.3.3.1 (and Table A.2-10): This page (and the table) presents exposure factors for the "Site Worker". More information should be provided in the narration as to the type of worker that is being considered. Section 2.2.3.1 describes the potential current receptor as being a site commercial/industrial worker yet Section 2.2.3.3.1 also mentions cutting grass. It is also unclear how a wading scenario fits in with a typical commercial/industrial worker exposure scenario. If a landscaper type of exposure is envisioned the soil ingestion rate of 50 mg/kg is too low. A more appropriate can be obtained from the RSL table which uses 100 mg/day for its "composite worker" scenario that is used to develop default industrial soil screening values, and that is also intended to capture exposure from landscaping activities.

5. Page 2-15, Section 2.2.3.3.2 (and Table A.2-10): The exposure duration for an adult hypothetical future resident should be 24 years instead of 30 years. Adult carcinogenic risk resulting from 24 years of exposure should be added to the child carcinogenic risk from 6 years of exposure so that a resident carcinogenic risk for a total of 30 years results. Note that mutagens have there own life-stage specific algorithms that incorporate 4 life stages beginning at birth and ending at 30 years.

6. Page 2-16, Section 2.2.3.3.3: What was the basis or rationale behind the statement that, *"Construction workers are not likely to come into contact with shallow groundwater during a hypothetical construction project, since the depth to shallow groundwater is at least 10 feet."* Was there any research to support the claim that trenches are not expected go deeper than 10 feet.

7. Page 2-19, Section 2.2.4.3: For the Study Areas where lead was a COPC the IEUBK results are presented without documentation. Please provide supporting information and documentation for the IEUBK model runs for these Study Areas.

Building Debris Disposal Trench (BDDT)

8. Page 3-2, Section 3.3: It is agreed that the sampling data from the riprap covered portion of the BDDT can be treated differently than other areas of the BDDT Study Area. However the usefulness of the statistical comparison between the riprap dataset to the remaining larger BDDT dataset is unclear. A more direct approach is to determine the risk associated with the riprap area data separately from the remaining BDDT area.

9. Page 3-9, Section 3.4.5 and included table: In this section it is reported that carcinogenic risk to the hypothetical future child resident from combined surface and subsurface soil is 1E-04 and therefore acceptable. Note that if carcinogenic risk was calculated for a combined adult/child resident using the mutagen equations discussed above the residential carcinogenic risk would be significantly greater than 1E-04.

Bag Loading Area (BLA)

10. Page 4-9, Section 4.4.4.3: Since PAHs are driving the unacceptable hypothetical future residential risk at this Study Area it is expected to be even higher when the above comment is taken into account.

11. Page 4-10: More documentation of the IEUBK modeling runs should be provided. The cited table (Table A.4.HHRA-18) only provides the predicted range of blood lead levels. There should be more information on model inputs provided. This comment applies to the other study areas where lead was COPC (i.e, the IAA and WBG).

Rail Yard (RY)

12. Page 6-10, Section 6.4.5: Please provide more information regarding the detection of PCP of 830 mg/kg, which is the driver for the unacceptable residential carcinogenic risk reported in this section. How extensive was the follow up investigation and attempts to duplicate the elevated hit?

Western Burning Ground (WBG)

13. Page 7-8, Section 7.4.1.5 and Table A.7.HHRA-5. How was it determined that the fish tissue sampling would be limited to only the metals listed on the table?

EXECUTIVE SUMMARY

ARCADIS U.S, Inc. (ARCADIS) has been retained by the United States Army Environmental Command (AEC) to perform Installation Restoration Program (IRP) activities at the Radford Army Ammunition Plant (RFAAP). IRP activities for both the Main Manufacturing Area (RFAAP-MMA) and the New River Unit (RFAAP-NRU) of the RFAAP facility are being conducted as part of a Performance Based Contract (PBC) awarded to ARCADIS under contract W91ZLK-05-D-0015: Task 0002. The RFAAP-NRU is managed under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA).

ARCADIS has prepared this Remedial Investigation (RI) Report to summarize the environmental investigation activities that have been performed at the RFAAP-NRU. Specifically, this report will discuss the investigation activities completed at five separate Study Areas that have been indentified at the RFAAP-NRU. The names/abbreviations for these sites are as follows:

- Building Debris Disposal Trench (BDDT)
- Bag Loading Area (BLA)
- Igniter Assembly Area (IAA)
- Rail Yard (RY)
- Western Burning Ground (WBG)

In addition to these five Study Areas, the RI report presents the findings of a facility-wide groundwater investigation conducted at the RFAAP-NRU. Potential effects to groundwater at the RFAAP-NRU are addressed on a facility-wide basis in this report instead of by individual Study Area.

A sixth Study Area at the RFAAP-NRU, the Northern Burning Ground (NBG), will not be discussed in this RI report. The investigation activities at the NBG have been completed and a removal action, which will be the final action for the site, will likely be completed in 2009 to address lead and chromium containing soil at that site. An *Engineering Evaluation/Cost Analysis* (EE/CA) for the NBG has been submitted to the Virginia Department of Environmental Quality (VDEQ). The EE/CA summarizes the historical investigations completed at the site and the results of site-specific human health and ecological risk assessments. The EE/CA also presents a summary of the removal action alternatives that were evaluated for the site prior to selection of the final remedy.

Environmental investigations have been ongoing at the five RFAAP-NRU Study Areas discussed in this report since 1997. This report presents the findings of each phase of investigation conducted at the site, including the most recent investigation activities completed by ARCADIS from 2008 to 2010. ARCADIS' 2008 investigation activities were performed in accordance with Remedial Investigation Work Plan Addendum 27 (ARCADIS 2008b). The 2009 investigation activities were completed in accordance with the June 2009 Supplemental Remedial Investigation Work Plan (ARCADIS 2009a). The 2010 groundwater investigation activities were completed in accordance with the Draft Supplemental Groundwater Investigation Work Plan (ARCADIS, 2010) In addition to summarizing the findings of the environmental investigation activities, this report includes a Human Health Risk Assessment (HHRA), Ecological Risk Assessment (ERA), and recommended path forward for each Study Area and groundwater. The major conclusions for each site are as follows:

BDDT – Residual polycyclic aromatic hydrocarbons (PAHs) that washed out of a debris disposal trench prior to 1998 site restoration activities have resulted in the presence of PAH compounds in downgradient soils. Soil sampling activities have delineated the extent of PAHs, which are confined to surface soil within an approximately 0.4-acre open area downgradient of the former disposal trench. PAHs are also present in the soils underneath a rip rap and geotextile liner installed in the disposal trench during the site restoration activities. Sediment and surface water samples collected from a creek at the downgradient end of the BDDT indicate that the PAHs present in the soils do not serve as a significant ongoing source of constituents to the creek. The HHRA performed for the site indicate that the risks were within acceptable ranges for industrial use of the site. However, benzo(a)pyrene and cobalt were found to be risk drivers under a residential land use scenario. Benzo(a)pyrene is present at concentrations above the United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) in many of the samples collected from the trench and downgradient areas. The cobalt risks were driven by one sample in the open area downgradient of the trench that had a cobalt concentration outside of the range of established background levels. Cobalt is a naturally occurring element present within the soils at the NRU, and there is no evidence that the isolated cobalt concentration driving the elevated risk at the BDDT is a result of human activity at the site; nor is there any evidence of elevated cobalt concentrations over a wider area. Therefore, it is unlikely that cobalt would present a true risk under hypothetical future residential land use scenarios. The ERA results indicated that no adverse effects were expected for wildlife. Based on the potential residential risks associated with the benzo(a)pyrene in surface soil located downgradient of the trench and the soil located under the rip rap covered portions of the trench, it is recommended that a FS be conducted to evaluate the available CERCLA response actions for the site. The response action alternative analysis will include an evaluation of potential actions to reduce risk to levels acceptable for residential use of the property, as well as options for maintaining the industrial use of the property.

BLA – Conductive flooring material located in site buildings has been exposed to weathering by the removal of building exteriors. As a result of weathering, the flooring material is deteriorating and washing onto surrounding soils. Sampling programs conducted at the BLA to evaluate the effects from the deteriorated conductive flooring, other building materials, and historical site operations have indicated the presence of asbestos and several inorganic constituents in soils surrounding site buildings at concentrations above applicable USEPA RSLs. PAHs and polychlorinated biphenyls (PCBs) were also detected in isolated samples from the site at concentrations above applicable screening levels. The extent of the detected inorganics, asbestos, and PCBs have been well delineated and are confined to surface soils in the immediate vicinity of the buildings, elevated walkways, and/or former transformer locations. Constituents do not appear to be migrating from the affected areas based on sediment and surface water samples collected from area drainage ditches and a nearby creek. The results of the HHRA activities indicated that predicted blood lead levels for an unborn fetus in a pregnant site worker would be the primary risk driver under an industrial land use scenario. Lead and copper were found to present unacceptable risks under the construction worker exposure scenario. Aroclor 1254, benzo(a)pyrene, cobalt, copper, and lead were also found to be risk drivers under a residential land use scenario. The ERA concluded that adverse population-level effects would not be expected due to the limited areal distribution of constituents and the low level of associated risk.

Although evaluated separately from the other constituents in the risk assessment, the asbestos identified in the degraded conductive flooring material and in soils surrounding BLA buildings could present a potential risk to current and future site workers or hypothetical future residents. Activity based sampling conducted at two of the BLA buildings (Buildings 404 and 411) has demonstrated that intensive soil disturbance activities in the areas adjacent to buildings with conductive flooring have the potential to generate airborne asbestos at concentrations above site specific Air Action Levels (AALs) for industrial receptors and hypothetical future residents. This potential appears to be limited to surface soils immediately adjacent to the buildings where conductive flooring has washed off of the building pads and asbestos concentrations in soil are highest. Although not evaluated in the risk assessment, asbestos in the remains of other building materials (e.g. pipe insulation, mastic, joint compound, etc.) could also present a risk to current and hypothetical future receptors if it becomes airborne.

An FS is recommended for the BLA to assess potential remedial alternatives to mitigate the risks and hazards associated with the site soils and conductive flooring material. While remedial actions for lead based paint and non-flooring asbestos will not be presented in the FS, land-use restrictions will be put in place to mitigate possible exposure to current and hypothetical future receptors from these materials.

IAA – The IAA site is very similar to the BLA in that conductive flooring material located in site buildings has deteriorated as a result of weathering due to the removal of building exteriors. The deteriorating flooring is contributing constituents, primarily inorganics and asbestos, to the surface soil adjacent to site buildings. PAHs and PCBs have also been detected at concentrations above USEPA RSLs next to a few site buildings and former transformer locations. Soil sampling has confirmed that the elevated concentrations are confined to surface soils throughout the majority of the site and that lateral and vertical migration is extremely limited. Sediment samples collected from dry storm water drainage ditches indicated isolated occurrences of some constituents (i.e., lead and PAHs) at concentrations above applicable screening levels. The results of the HHRA activities indicated that risks, hazards, and predicted blood lead levels were within acceptable ranges under the industrial land use scenarios. However, the HHRA indicated that under the residential land use scenarios there were risks and hazards above the generally acceptable limits, primarily due to Aroclor 1254, copper, cobalt, and 2,4-dinitrotoluene detections in soil. Lead was also found to contribute to an elevated fetal blood level under the residential land use scenario. The ERA concluded that adverse population-level effects would not be expected at the IAA due to the limited areal distribution of constituents and the low level of associated risks.

Although evaluated separately from the other constituents in the risk assessment, the asbestos identified in the degraded conductive flooring material and in soils near IAA buildings could present a potential risk to current and future site workers or hypothetical future residents. Activity based sampling conducted IAA Building 8102-1 has demonstrated that intensive soil disturbance activities in the areas where conductive flooring has washed off building pads have the potential to generate airborne asbestos at concentrations above site specific AALs for industrial receptors and hypothetical future residents. This potential appears to be limited to surface soils immediately adjacent to the buildings where conductive flooring has washed off of the building pads and asbestos concentrations in soil are highest. Although not evaluated in the risk assessment, asbestos in the remains of other building materials (e.g. pipe insulation, mastic, joint compound, etc.) could also present a risk to current and hypothetical future receptors if it becomes airborne.

An FS is recommended for the IAA to assess potential remedial alternatives to mitigate the risks and hazards associated with the site soils and conductive flooring material. While remedial actions for lead based paint and non-flooring asbestos will not be presented in the FS, land-use restrictions will be put in place to mitigate possible exposure to current and hypothetical future receptors from these materials.

RY – A limited number of constituents were detected sporadically at concentrations above applicable RSLs during the course of environmental investigation at the RY. However, the findings of the HHRA indicated that the potential health risks for the site are within or below USEPA's target risk range under both industrial and future hypothetical residential land use scenarios. Minimal ecological risks were driven by constituents that were detected sporadically in a relatively small portion of the site. Based on the results of the risk assessments there is no need to place any restriction on the current use or future development of the site. Therefore, No Action is recommended for this site.

WBG – The WBG was a former burning ground site that was used to dispose of off-spec materials and materials exposed to energetic/explosive compounds. Surface soils containing ash material, lead and other constituents were removed from the former burning area and replaced with clean fill during a 1999 test pitting program; therefore, subsequent investigations focused on areas outside of the burn area. Investigations included delineating an ashy layer of material under the pond access road, surface and subsurface soils outside of the former burning ground, pond sediments and surface water, and downgradient stream sediments and surface water. The risk assessment concluded that potential human health risks were within acceptable USEPA risk ranges under the current/future industrial land use scenario, and future recreational use of the pond including a fishing rodeo, but that chromium and lead detected in pond sediment samples contributed to potential unacceptable risk levels under a future hypothetical residential land use scenario. The chromium and lead concentrations contributing to the elevated risk levels are confined to an approximately 2,100 square foot (ft^2) area (0.05 acres) near the northern bank of the 3.5-acre pond. The ERA concluded that no adverse ecological effects would be expected on a population level due to the limited distribution of constituents of potential concern (COPCs). Based on the potential residential risks associated with the lead and chromium in the pond sediments, it is recommended that a FS be conducted to evaluate the available CERCLA response actions for the site. The response action alternative analysis will include an evaluation of potential actions to reduce risk to levels acceptable for residential use of the property, as well as options for maintaining the industrial use of the property.

Groundwater – The groundwater investigation activities at the RFAAP-NRU included the installation of 11 groundwater monitoring wells, three groundwater sampling events (2007, 2008, and 2010), and the development of a conceptual site model (CSM) based on all historical information collected from the facility. The 2008 and 2010 sampling activities included the collection of samples from four springs within the boundaries of the RFAAP-NRU in addition to the 11 groundwater monitoring wells. The 2008 groundwater investigation activities also included the attempted installation of a monitoring well at the BDDT; however, this attempt was abandoned because groundwater was not encountered in either of two borings completed to 75 feet below ground surface (ft bgs) through competent bedrock. Inorganics were detected at concentrations above tap water RSLs in groundwater samples collected from several monitoring wells. The elevated concentrations in these wells have been attributed to the presence of suspended solids in the groundwater samples and naturally occurring metals in the formation. Analysis of samples collected with low turbidity and samples that were collected after filtering did not have any inorganics at concentrations above applicable tap water RSLs. The risk assessment concluded that arsenic detected in groundwater samples in 2007, 2008, and 2010 resulted in unacceptable potential risks under the future hypothetical residential land use scenario. However, arsenic was only detected in unfiltered groundwater sample that had elevated turbidity, which is highly conservative and not reflective of conditions most likely to occur in groundwater that would be used for residential or commercial uses. Several dioxin congeners detected in groundwater samples during the 2007 sampling event also resulted in unacceptable risks under the future hypothetical residential land use scenario. However, it should be noted that 1) the dioxin concentrations reported in these groundwater samples were an order of magnitude less than the federal drinking water level; 2) dioxins were detected in a laboratory blank sample associated with the 2007 samples and the detections in groundwater are likely the result of cross contamination at the laboratory; and 3)dioxins were not detected in the confirmation groundwater samples collected in 2010.

Spring water samples were collected at the RFAAP-NRU during 2008 and 2010. Laboratory analysis results indicate that the detected constituents were present at concentrations less than applicable tap water screening levels. Spring water samples are considered to be an excellent indicator of overall groundwater quality due to the springs function as groundwater discharge points for relatively large areas. No Action is recommended for groundwater at the RFAAP- NRU.

1. Introduction

ARCADIS U.S, Inc. (ARCADIS) has been retained by the United States Army Environmental Command (AEC) to perform Installation Restoration Program (IRP) activities at the Radford Army Ammunition Plant (RFAAP). The RFAAP facility is located in Montgomery and Pulaski Counties in southwestern Virginia and consists of two noncontiguous units: the New River Unit (NRU) and the Main Manufacturing Area (MMA). The RFAAP-MMA is located approximately 5 miles northeast of the City of Radford, Virginia. The RFAAP-NRU is located about six miles southwest of the RFAAP-MMA, near the town of Dublin, Virginia (Figure 1-1). IRP activities for both the RFAAP-MMA and the RFAAP-NRU are being conducted as part of a Performance Based Contract (PBC) awarded to ARCADIS under contract W91ZLK-05-D-0015: Task 0002. The RFAAP-NRU is managed under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA).

ARCADIS has prepared this Remedial Investigation (RI) Report to summarize the environmental investigation activities that have been performed at the RFAAP-NRU. Specifically, this report will discuss the investigation activities completed at five separate Study Areas that have been indentified at the RFAAP-NRU. The names/abbreviations for these sites are as follows:

- Building Debris Disposal Trench (BDDT),
- Bag Loading Area (BLA),
- Igniter Assembly Area (IAA),
- Rail Yard (RY), and
- Western Burning Ground (WBG).

In addition to these five Study Areas, the RI report will present the findings of a facility-wide groundwater investigation conducted at the RFAAP-NRU. Potential effects to groundwater at the RFAAP-NRU will be addressed on a facility-wide basis in this report instead of by individual Study Area.

A sixth Study Area at the RFAAP-NRU, the Northern Burning Ground (NBG), will not be discussed in this report. The investigation activities at the NBG have been completed and a removal action will be completed in 2009 to address lead and chromium containing soil at that site. An *Engineering Evaluation/Cost Analysis* (EE/CA) for the NBG has been submitted to the Virginia Department of Environmental Quality (VDEQ). The EE/CA summarizes the historical investigations completed at the site and the results of site-specific human and ecological risk assessments. The

EE/CA also presents a summary of the removal action alternatives that were evaluated for the site prior to selection of the final remedy.

1.1 Facility Overview

The RFAAP-NRU facility is located in the mountains of southwestern Virginia in the Great Valley subprovince of the Valley and Ridge Physiographic Province. The RFAAP-NRU encompasses approximately 2,813 acres of Pulaski County, Virginia, near the town of Dublin (Figure 1-1). The RFAAP-NRU was constructed in 1940 and was originally known as the New River Ordinance Works (NROW). The facility operated as a bag manufacturing and loading plant for artillery, cannon, and mortar projectiles during World War II. Active manufacturing operations ceased in 1945, at the completion of the war, and the facility was incorporated into the RFAAP. The RFAAP-NRU now serves as a storage facility for operations at the MMA.

A total of six Study Areas have been indentified at the RFAAP-NRU as having the potential for adverse environmental effects associated with historical operations at the site. Five of these Study Areas, the BDDT, BLA, IAA, RY, and WBG are discussed in this report. The sixth area, known as the NBG, has been addressed under a Non Time Critical Removal Action and a separate EE/CA has been submitted for that site. The locations of the various Study Areas at the RFAAP-NRU are depicted in Figure 1-2.

1.2 Study Areas

1.2.1 Building Debris Disposal Trench

The BDDT is a former ephemeral unlined natural drainage channel located in the southern portion of the RFAAP-NRU (Figure 1-2). The trench directs surface water runoff from the surrounding area towards an unnamed stream that flows through the southern portion of the RFAAP-NRU. The trench was previously utilized as a disposal site for miscellaneous building debris generated during the dismantling of old buildings at the RFAAP-NRU facility. The building debris and any visibly stained soil was removed from the trench in 1998, replaced with clean fill, lined with a geotextile fabric, and covered with riprap. Investigations in this Study Area have focused on characterizing and delineating the effects to environmental media (i.e., soil, sediment, and surface water) in areas within and downgradient of the former disposal area trench. The physical characteristics and history of the BDDT are discussed in greater detail within Section 5 of this report.

1.2.2 Bag Loading Area (BLA)

The BLA is located along the southwestern boundary of the RFAAP-NRU (Figure 1-2). The BLA ran two powder bag loading production lines from 1941-1943. Thirteen buildings were once located onsite; however, all process equipment, wooden roofs, and wooden walls have been removed from the buildings, leaving only concrete slabs and cinder block walls. These buildings are referenced later in this report with their former building numbers. The concrete slab floors in several of the buildings (including the second story floors of two buildings) were covered in a conductive cement-like material containing various metals and asbestos. This conductive flooring was used to prevent the build-up of static charges in areas where energetic materials were handled. Removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and break away from the underlying concrete. In many cases, the flooring has degraded into a red powder-like material and washed onto the surrounding soils. Investigations in this Study Area have focused on characterizing the effects that the degrading flooring material and historical site operations have had on environmental media (i.e., soil, sediments, and surface water) in areas surrounding and downgradient of the buildings. The investigations have also included an assessment of former electrical transformers that were located at the BLA. The physical characteristics and history of the BLA are discussed in greater detail within Section 6 of this report.

1.2.3 Igniter Assembly Area (IAA)

The IAA is located in the western portion of the RFAAP-NRU (Figure 1-2). Buildings at the site were used for igniter assembly, as well as the shipping and receiving of materials related to the IAA. The area was active from approximately 1941 through 1943. Process equipment and wooden walls and roofs have been removed. The remains consist of concrete foundations and walls and are referenced later in this report with their former building numbers. The main igniter assembly buildings and multiple outparcel buildings at the IAA had a conductive flooring material similar to the BLA. The conductive flooring was exposed to the weather when the wooden roof and walls were removed from the buildings. As a result, the conductive flooring has degraded into a red powder-like substance very similar to what has been observed at the BLA. In many areas, the degraded conductive flooring material has washed off the concrete pads onto surrounding surface soils. Investigations in this Study Area have focused on characterizing the effects that the degrading flooring material and historical site operations have had on environmental media (i.e., soil, sediments, and surface water) in areas surrounding and downgradient of the buildings. The investigations have also included an assessment of former electrical transformers that were located at the IAA. The physical characteristics and history of the IAA are discussed in greater detail within Section 7 of this report.

1.2.4 Rail Yard

The RY is a former loading and unloading area for rail cars located in the southwestern portion of the RFAAP-NRU, east of the IAA and WBG (Figure 1-2). The RY consists of three sets of tracks, three open transfer platforms, and one decommissioned sewer line. Two small streams run north to south through the RY and drain into the unnamed stream immediately upstream of the BDDT. Investigations in this Study Area have focused on characterizing the potential effects that historical site operations may have had on environmental media (i.e., soil, sediments, and surface water) within and downgradient of the RY. The investigations have also included an assessment of former electrical transformers that were located at the RY. The physical characteristics and history of the RY are discussed in greater detail within Section 8 of this report.

1.2.5 Western Burning Ground

The WBG is a former burning ground located south of the IAA in the southwestern portion of the RFAAP-NRU (Figure 1-2). The WBG was used as a burning ground to decontaminate explosives contaminated material and to dispose of excess and off-spec explosives/energetics. The main burn area was approximately 170 feet (ft) long by 100 ft wide and is surrounded on three sides by an approximately 4 ft high earthen berm. A test pitting program was conducted at the site in 1998 that effectively removed all soils within the former burn area that may have been affected by the historical burning operations. The excavated soils were replaced with clean fill. Investigations at the WBG have focused on characterizing the effects that historical site operations may have had on environmental media (i.e., soil, sediments, and surface water) within and surrounding the former burning site. Extensive investigations have been conducted within a small pond, and downgradient stream, located adjacent to the WBG site that receives rain water runoff from the site and surrounding area. The physical characteristics and history of the WBG are discussed in greater detail within Section 9 of this report.

1.2.6 Northern Burning Ground

The NBG is a former burning ground located in the northwestern portion of the RFAAP-NRU near Gate 20 (Figure 1-2). The NBG appears to have been in limited use as a burning ground. No structures appear on the site, and the burning operations were apparently confined to a small area at the center of the site. Surface water at the NBG flows toward a drainage ditch that runs parallel to a paved surface road to the north of the site. The physical characteristics and results of historical investigations at the NBG are presented in a separate EE/CA that has been prepared for that site and will not be discussed further within this report.

1.3 Investigation Overview

Characterization of the environmental conditions at each of the five Study Areas discussed in this report has been ongoing since 1997. The groundwater investigation activities for the RFAAP-NRU facility began in 2007. The earliest site investigations were conducted for the sole purpose of identifying the potential presence of contaminants associated with historical land uses at the Study Areas. Subsequent site investigations were conducted to further characterize and delineate the extent of elevated constituent concentrations at each of the Study Areas. The most recent investigation activities were completed by ARCADIS in 2008, 2009, and 2010 in accordance with the June 2008 Remedial Investigation Work Plan Addendum 27 (ARCADIS 2008b), the June 2009 Supplemental Remedial Investigation Work Plan (ARCADIS 2009a), and the April 2010 Supplemental Groundwater Investigation Work Plan (ARCADIS 2010). These investigations were performed for the purpose of:

- Completing the delineation of constituents detected at concentrations above applicable screening levels;
- Indentifying potential effects to groundwater at the facility and assisting in the development of a robust conceptual site model (CSM);
- Characterizing the potential risks with asbestos in soil at the BLA and IAA Study Areas; and
- Finalizing the site characterization work so as to facilitate the completion of site specific human-health risk assessments (HHRAs) and ecological risk assessments (ERAs).

The site investigation activities at the RFAAP-NRU have identified various constituents in soil, sediment, surface water, and groundwater at the Study Areas including: volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), dioxins and furans, explosives, herbicides, pesticides, polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), and inorganics. The findings of the various phases of environmental investigation conducted at RFAAP-NRU are discussed on a site-by-site basis in later sections of this report.

1.4 Report Organization

This Remedial Investigation Report is divided in to the following sections:

- **Section 1 – Introduction.** This section provides background information related to the RFAAP-NRU environmental investigations.

- **Section 2 – Scope of Field Investigations.** This section provides a brief history of the site investigation activities that that have been conducted at the RFAAP-NRU; with a focus on the activities completed in 2008 and 2009 to complete the remedial investigation process for the facility.

- **Section 3 – Environmental Setting and Conceptual Site Model.** This section provides a brief discussion of the environmental setting at the RFAAP-NRU and presents the framework of the conceptual model that has guided the environmental investigations and risk assessment activities at the facility.

- **Section 4 – Methods and Procedures for Data Evaluation.** This section discusses the methods and procedures used during the evaluation of the data collected during the various phases of environmental investigation. This includes a summary of the human-health and ecological risk assessment activities, which are also presented in greater detail within Appendix A.

- **Sections 5 through 10 – Site Discussions.** These sections present the site characteristics, summaries of environmental investigations, the nature extent of contamination, the human health risk assessment (HHRA), the ecological risk assessment (ERA), and the conclusions for each of the Study Areas and for facility-wide groundwater.

- **Section 11 – Conclusions and Recommendations.** As indicated by the title, this section presents a summary of the conclusions drawn from the remedial investigation and recommended paths forward.

- **Section 12 – References**.

2. Scope of Field Investigations

2.1 Historical Investigations

As discussed in Section 1.3, characterization of the environmental conditions at the RFAAP-NRU has been on-going since 1997 and has included multiple phases of investigation. Between 1997 and 2007, extensive site investigation activities were completed at the RFAAP-NRU by several different entities, including Alliant Techsystems, Inc. (ATK); Gannett Fleming, Inc. (Gannet Fleming); ICF Kaiser Engineers, Inc. (ICF KE); Shaw Environmental, Inc. (Shaw); and the United States Army Corps of Engineers (USACE). The investigation activities conducted by these entities typically focused on surface soil, subsurface soil, sediments, surface water, and source materials at the six different Study Areas at the RFAAP-NRU (BDDT, BLA, IAA, NBG, RY, and WBG). In 2007 Shaw expanded the investigation to include facility wide groundwater through the installation and sampling of eleven groundwater monitoring wells located throughout the facility. Sample matrices that detail the environmental samples collected during each phase of investigation completed at the BDDT, BLA, IAA, RY, WBG, and for facility-wide groundwater are presented in Tables 2-1 through 2-6, respectively. The details and findings of the various phases of historical investigations conducted at the BDDT, BLA, IAA, RY, WBG, and facility-wide groundwater are discussed in further detail within in Sections 5 through 10 of this report. Appendix B provides a summary of all samples that have been collected for the BDDT, BLA, IAA, RY, WBG and groundwater investigation, which includes the sample date, depth, and location coordinates.

2.2 ARCADIS Investigation 2008

In 2008, AEC retained ARCADIS to complete the RI process for the RFAA-NRU as part of the overall IRP for the facility. ARCADIS reviewed the historical information obtained during the investigation activities completed between 1997 and 2007 and developed a work plan for finalizing the remedial investigation at each of the different Study Areas and for facility-wide groundwater. The details of this plan were submitted to VDEQ in June 2008 in the document entitled *DRAFT Remedial Investigation Work Plan Addendum 27* (ARCADIS 2008b). The field investigation activities outlined in this work plan were completed between July and October 2008. Additional investigation activities were completed at the BLA and IAA sites in July 2009 to further characterize potential risks associated with asbestos in soil. The field investigation activities for the 2009 asbestos investigation are outlined in the Supplemental Remedial Investigation Work Plan (ARCADIS 2009a). The sample locations included in the 2008 and 2009 site investigations are summarized in Appendix B. The following sections provide a brief discussion of the activities completed at each of the Study Areas.

2.2.1 Building Debris Disposal Trench

Review of the historical data sets collected at the BDDT between 1997 and 2004 indicated that soils in the open area downgradient of the former disposal trench contained PAHs at concentrations above applicable screening levels. PAHs had also been detected at concentrations above screening levels in historical sediment samples collected from the creek downgradient of the trench. In order to complete the remedial investigation activities for the BDDT, ARCADIS collected the following samples in 2008:

- Two soil borings were completed at the downgradient extent of the former disposal trench to evaluate the vertical extent of PAHs in subsurface soil. Samples were collected at depths of 0-1 feet below ground surface (ft bgs), 2-3 ft bgs, and 3-4 ft bgs, at both soil borings using dedicated hand augers. Bedrock was encountered at a depth approximately 5 ft at both borings; therefore, deeper samples were not collected. All of the samples were analyzed for PAHs by USEPA Method 8270.

- Six surface soil samples were collected from the perimeter of the open area between the disposal trench and downgradient creek to ensure that the horizontal extent of PAHs in surface soil had been defined. The surface soil samples were collected from ground surface to a depth of 0.5 ft bgs, using dedicated soil sampling scoops. All of the samples were analyzed for PAHs by USEPA Method 8270.

- Four sediment samples were collected from the creek in the proximity of historical locations that had contained PAHs. These samples were collected to evaluate concentration trends within the creek sediments and to determine if the creek was being affected by continued release of PAHs from soils in the BDDT area. The sediment samples were collected at depths of 0-0.5 ft bgs at each location using dedicated plastic soil sampling scoops and were analyzed for PAHs by USEPA Method 8270.

- Surface water samples were collected from each of the four sediment sample locations to evaluate whether surface water quality in the creek was affected by PAHs from the BDDT area. The surface water samples were all analyzed for PAHs by USEPA Method 8270.

A complete summary of the samples collected at the BDDT during the 2008 investigation is included within the historical sampling matrix presented in Table 2-1. Further details on ARCADIS' investigation activities are presented in Section 5 of this report, along with the findings of the historical investigations conducted at the site. Section 5 of this report also presents a summary of the human-health and ecological risk assessments that were conducted for the site based on the combined data sets collected throughout the course of investigation.

2.2.2 Bag Loading Area

Review of the historical data sets collected at the BLA between 1997 and 2004 indicated that surface soils in the vicinity of buildings with conductive flooring material were the primary areas of concern at the site. The data indicated that several different metals had been detected at concentrations above applicable screening levels in surface soil. Asbestos and PAHs were also identified in surface soils around buildings and former elevated walkway platforms. In addition, the PCB Aroclor 1254 was detected in two historical sample locations (one near a former transformer and one near a site building) at concentrations above applicable screening levels. The historical data did not indicate any signs of adverse effects in subsurface soil, sediment, or surface water in the vicinity of the BLA. In order to complete the remedial investigation at the BLA, ARCADIS completed the following activities in 2008:

- Performed an inventory of the buildings at the BLA to identify buildings with conductive flooring, including those that may not have appeared on historic site maps. The locations of all buildings were surveyed utilizing GPS equipment and measurements were collected of the building dimensions. The building inventory identified seven buildings with conductive flooring material. In total approximately 19,000 ft^2 of conductive flooring material is present at the site.

- Based on review of historical analytical data sets from the BLA, it was determined that lead could be used as a good indicator of where other constituents may also be present in surface soil as a result of the deteriorating conductive flooring. Therefore, ARCADIS conducted a field screening program that utilized a hand-held X-Ray Fluorescence (XRF) meter to screen surface soil samples around site buildings for lead. The field screening program included the collection of surface soil samples (0 - 0.5 ft bgs) around the perimeter of all site buildings with conductive flooring material. Samples were typically collected in rows of three screening points spaced at 1 ft, 5 ft, and 10 ft distances from the building footprint. In cases where the XRF result indicated a lead concentration above 400 mg/kg, samples were also collected further away from the building (i.e., 15 ft and 20 ft). The rows were located on approximately 25 ft centers around the perimeter of each building, with a bias towards preferential flow paths off of the building pads (i.e., where red staining was present in soil). A total of 63 rows containing 192 individual points were screened with the XRF.

- In order to evaluate the quality of the XRF screening results and to provide additional characterization data, 19 of the 192 XRF screening samples were also submitted for laboratory analysis. A minimum of one sample was collected at each building identified with conductive flooring. These samples were submitted for laboratory analysis of TAL inorganics (USEPA Method 6010B) and SVOCs (USEPA Method 8270). The samples were also analyzed for the presence of asbestos using polarized light microscopy (PLM) and USEPA Method 600/R-93 sample preparation. Five of these samples were submitted for laboratory analysis of TCLP-inorganics (USEPA Method 6010B) to assist in evaluating any potential future removal alternatives. Comparison of the XRF field screening results generally indicated a good correlation between the XRF results and the results of the laboratory reported lead concentrations, with the XRF results typically biased slightly high. Additional discussion of the correlation between the XRF data and laboratory results is presented in Section 6.

- Four surface soil samples (0 – 0.5 ft bgs) were collected from the central area of the BLA in the vicinity of a former elevated walkway. The samples were collected to evaluate historical surface soil detections of PAHs at concentrations above applicable screening criteria within this area. The 2008 surface soil samples were collected using dedicated soil sampling scoops and were analyzed for PAHs by USEPA Method 8270.

- Two surface soil samples and two subsurface soil samples were collected in the vicinity of a former sample location on the north side of Building 405 where the PCB Aroclor 1254 had been detected above applicable screening levels in 2002. These samples, which were analyzed for PCBs by USEPA Method

8082, were collected for the purpose of delineating potential PCBs associated with the historical sample.

- Two surface soil samples were collected in the vicinity of a former transformer on the east side of Building 416 where the PCB Aroclor 1254 had been detected above applicable screening levels in 2002. These samples, which were analyzed for PCBs by USEPA Method 8082, were collected for the purpose of delineating potential PCBs associated with the historical sample.

- During the 2008 site investigation at the BLA subsurface utility vaults were identified at two of the BLA Buildings (Buildings 404 and 405). These subsurface utility vaults run around the perimeter of the buildings, underneath the surrounding sidewalks. Visual inspection of the vaults indicated that they contained approximately 1 ft of standing water, but little to no sediment. A surface water grab sample was collected from the vault at Building 405 utilizing a dedicated plastic bailer and analyzed for VOCs by USEPA Method 8260, PAHs by USEPA Method 8270, and inorganics by USEPA Method 6010B, to evaluate the potential presence of contaminants in the water.

- During the 2008 investigation, surface water, degraded flooring material, and sediment were observed in a former elevator shaft pit inside Building 405. In order to evaluate if contaminants were present in this pit, one sediment sample and one surface water sample were collected. Both the sediment sample and the surface water sample were analyzed for PAHs by USEPA Method 8270 and inorganics by USEPA Method 6010B.

ARCADIS returned to the BLA in July 2009 to conduct an additional investigation designed to facilitate the evaluation of potential health risks associated with asbestos in soil. This investigation was conducted in accordance with the June 2009 Supplemental Remedial Investigation Work Plan and included the following activities:

- In order to further define the concentration and extent of the asbestos in soil, delineation soil samples were collected at select surface soil locations where asbestos had previously been detected or at buildings that lacked historical data. The samples were collected at distances of 1, 5, 10, 15, and 20 ft from buildings and analyzed sequentially. The samples were analyzed for asbestos by transmission electron microscopy (TEM) via USEPA method 600/R-93/116 with sample preparation using California Air Resources Board (CARB) Method

435 and an analytical sensitivity of 0.1% (TEM CARB Level B). This analyses allowed for a quantitative evaluation of asbestos content in soil

- In an effort to evaluate the risk of exposure to airborne asbestos fibers resulting from asbestos in soil, ARCADIS conducted an activity based sampling program at two of the BLA buildings (Buildings 404 and 411). This sampling program, which utilized the USEPA recommended general action scenario of raking, was performed in accordance with USEPA *SOP 2094: Activity-Based Air Sampling for Asbestos* (USEPA, 2007c) and *Framework for Investigating Asbestos-Contaminated Superfund Sites* (USEPA, 2008g). The sampling program included the following components:

  - Two 10 ft by 10 ft sample grids were set up at Building 404 in an area that has had historic asbestos locations. The first grid was located 0-10 ft from the edge of the building and the second was located 10-20 ft from the building.

  - A second pair of 10 ft by 10 ft sample grids was set up at Building 411 in another area that has had historic asbestos detections. These grids were also located 0-10 ft and 10-20 ft from the building edge.

  - Soil samples were collected from the centerline of each sampling grid pair at locations of 1, 5, 10, 15, and 20 feet from Buildings 404 and 411. These samples were collected from a depth of 0-3 inches. The samples were analyzed for soil moisture by ASTM Method D2216-05, Grain Size by ASTM Method D6913-04e, and asbestos by TEM CARB Level B) to establish soil conditions and asbestos concentrations in the grid.

  - Each grid was vigorously raked by a participant wearing Level C personal protection equipment, so that the soil was disturbed. During the raking activity, the participant wore a personal air monitoring pump fitted with a 0.8 µm mixed cellulose ester (MCE) filter and sampling tube mounted in the subjects breathing zone. A stationary air monitoring pump fitted with a 0.8µm filter and sampling tube mounted at a height of 5 feet was also set on the downwind perimeter of the grid to collect air samples during the raking activity. The raking activity was performed for a duration that allowed at least 750 to 1,000 liters of air to be pulled through the filters. The filters from the personal pump and stationary pump were both submitted for laboratory analysis of asbestos by TEM Method 10312. The filters from the background pumps were both submitted for laboratory analysis of asbestos by TEM Method 10312.

- Background air samples were collected at Buildings 404 and 411 during the activity based sampling events to evaluate potential background interferences. The background samples were collected from an area upwind of the activity based sampling grids using a stationary air monitoring pump fitted with at 0.8 µm MCE filter.

A complete summary of the samples collected at the BLA during the 2008 and 2009 investigations are included within the historical sampling matrix presented in Table 2-2. Further details on ARCADIS' investigation activities are presented in Section 6 of this report, along with the findings of the historical investigations conducted at the BLA. Section 6 of this report also presents a summary of the human-health and ecological risk assessments that were conducted for the BLA based on the combined data sets collected throughout the course of investigation.

2.2.3 Igniter Assembly Area

The IAA is very similar to the BLA in that the conductive flooring material present at this site appears to be the primary source of potential adverse effects to environmental media. Review of the historical data sets collected at the IAA between 1997 and 2004 indicated that surface soils in the vicinity of buildings with conductive flooring material were the primary areas of concern at the site. The data indicated that several different metals and asbestos had been detected at concentrations above applicable screening levels in surface soil around site buildings. Other areas of potential concern identified during the historical data review included undelineated PCB and PAH detections in the vicinity of Building 8101, and undelineated lead detections in two area surface water drainage ditches. In order to complete the remedial investigation at the IAA, ARCADIS completed the following activities in 2008:

- ARCADIS performed an inventory of the buildings at the IAA to identify buildings with conductive flooring, including those that may not have appeared on historic site maps. The locations of all buildings were surveyed utilizing GPS equipment and measurements were collected of the building dimensions. The building inventory identified a total of 35 buildings at the IAA, 27 of which contained conductive flooring material. In total approximately 25,000 ft^2 of conductive flooring material is present at the site.

- Based on review of historical analytical data sets from the IAA, it was determined that lead could be used as a good indicator of where other constituents may also be present in surface soil as a result of the deteriorating conductive flooring. Therefore, a field screening program was conducted that utilized a hand-held X-Ray Fluorescence (XRF) meter to screen surface soil samples around site buildings for lead. The field screening program included the collection of surface soil samples (0 - 0.5 ft bgs) around the perimeter of all site buildings with conductive flooring material. Samples were typically collected in rows of three screening points spaced at 1 ft, 5 ft, and 10 ft distances from the building footprint. In cases where the XRF result indicated a lead concentration above 400 mg/kg, samples were also collected further away from the building (i.e., 15 ft and 20 ft). The rows were located on approximately 25 ft centers around the perimeter of each building, with a bias towards preferential flow paths off of the building pads (i.e., where red staining was present in soil). A total of 157 rows containing 475 individual points were screened with the XRF.

- In order to evaluate the quality of the XRF screening results and to provide additional characterization data, samples for laboratory analysis were collected from 41 of the 475 XRF screening locations. A minimum of one sample was collected at each building identified with conductive flooring. These samples were submitted for laboratory analysis of TAL inorganics (USEPA Method 6010B) and SVOCs (USEPA Method 8270). The samples were also analyzed for the presence of asbestos by PLM. Five of these samples were also submitted for laboratory analysis of TCLP-inorganics (USEPA Method 6010) to assist in evaluating any potential future removal alternatives. Comparison of the XRF field screening results generally indicated a good correlation between the XRF results and the results of the laboratory reported lead concentrations. Additional discussion of the correlation between the XRF data and laboratory results is presented in Section 7.

- XRF field screening and laboratory analytical samples were collected from two IAA drainage ditches where lead was detected at concentrations above applicable screening levels during a site investigation in 2002. One of the drainage ditches was located in the central portion of the IAA and the other was at the outfall of a culvert in the northeastern portion of the IAA. The samples were collected for the purpose of delineating the extent of lead within the ditches. A total of 9 screening samples were collected from these drainage ditches, and four of the screening samples (two from each ditch) were also submitted for laboratory analysis of TAL inorganics by USEPA Method 6010B. All samples were collected from depths of 0 – 0.5 ft bgs using dedicated soils sampling scoops.

- Two surface soil samples and one subsurface soil sample were collected from an area near the northwest corner of Building 8101 where the PCB Aroclor 1254 and several PAHs were detected at concentrations above applicable screening levels in a surface soil sample during the 2002 site investigation. The surface soil samples were collected from depths of 0 – 0.5 ft bgs using dedicated soil sampling scoops, and the subsurface soil sample was collected from a depth of 2 – 3 ft bgs using a dedicated hand auger. These samples were collected to evaluate the areal and vertical extent of the previously detected constituents at concentrations above screening levels. The samples were all analyzed for PAHs by USEPA Method 8270 and PCBs by USEPA Method 8082.

- During the 2008 site investigation at the IAA subsurface utility vaults were identified at IAA Buildings (Buildings 502, 504, 522, and 522A). These utility vaults run around the perimeter of the buildings underneath the surrounding sidewalks. Visual inspection of the vaults indicated that they contained approximately 1 ft of standing water, but little to no sediment. A water sample was collected from the vault at Building 522 and submitted for laboratory analysis for VOCs (USEPA Method 8260), PAHs (USEPA Method 8270), and TAL inorganics (USEPA Method 6010) to determine if contaminants were present in the water.

ARCADIS returned to the IAA in July 2009 to conduct an additional investigation designed to facilitate the evaluation of potential health risks associated with asbestos in soil. This investigation was conducted in accordance with the June 2009 Supplemental Remedial Investigation Work Plan and included the following activities:

- In order to further define the concentrations and extent of the asbestos in soil, delineation soil samples were collected at select surface soil locations where asbestos had previously been detected or at buildings that lacked historical data. The samples were collected at distances of 1, 5, 10, 15, and 20 ft from buildings and analyzed sequentially until no detection was reported. The samples were analyzed for asbestos by transmission electron microscopy (TEM) via USEPA method 600/R-93/116 with sample preparation using California Air Resources Board (CARB) Method 435 and an analytical sensitivity of 0.1% (TEM CARB Level B). This analyses allowed for a quantitative evaluation of asbestos content in soil

- In an effort to evaluate the risk of exposure to airborne asbestos fibers resulting from asbestos in soil, ARCADIS conducted an activity based sampling program at two of the IAA buildings (Buildings 8102-1 and 5). This sampling program, which utilized the USEPA recommended general action scenario of raking, was performed in accordance with USEPA *SOP 2094: Activity-Based Air Sampling for Asbestos* (USEPA, 2007c) and *Framework for Investigating Asbestos-Contaminated Superfund Sites* (USEPA, 2008g). The sampling program included the following components:

    - Two 10 ft by 10 ft sample grids were set up at Building 8102-1 in an area that has had historic asbestos locations. The first grid was located 0-10 ft from the edge of the building and the second was located 10-20 ft from the building.

    - A second pair of 10 ft by 10 ft sample grids was set up at Building 5 in another area that has had historic asbestos detections. These grids were also located 0-10 ft and 10-20 ft from the building edge.

    - Soil samples were collected from the centerline of each sampling grid pair at locations of 1, 5, 10, 15, and 20 feet from Buildings 8102-1 and 5. These samples were collected from a depth of 0-3 inches. The samples were analyzed for soil moisture by ASTM Method D2216-05, Grain Size by ASTM Method D6913-04e, and asbestos by TEM CARB Level B) to establish soil conditions in the grid.

    - Each grid was vigorously raked by a participant wearing Level C personal protection equipment, so that the soil was disturbed. During the raking activity, the participant wore a personal air monitoring pump fitted with a 0.8 µm mixed cellulose ester (MCE) filter and sampling tube mounted in the subjects breathing zone. A stationary air monitoring pump fitted with a 0.8µm filter and sampling tube mounted at a height of 5 feet was also set on the downwind perimeter of the grid to collect air samples during the raking activity. The raking activity was performed for a duration that allowed at least 750 to 1,000 liters of air to be pulled through the filters. The filters from the personal pump and stationary pump were both submitted for laboratory analysis of asbestos by TEM Method 10312.

- Background air samples were collected at Buildings 8102-1 and 5 during the activity based sampling events to evaluate potential background interferences. The background samples were collected from an area upwind of the activity based sampling grids using a stationary air monitoring pump fitted with at 0.8 µm MCE filter. The filters from the background sample pumps were both submitted for laboratory analysis of asbestos by TEM Method 10312.

A complete summary of the samples collected at the IAA during the 2008 and 2009 investigations is included within the historical sampling matrix presented in Table 2-3. Further details on ARCADIS' investigation activities are presented in Section 7 of this report, along with the findings of the historical investigations conducted at the IAA. Section 7 of this report also presents a summary of the human-health and ecological risk assessments that were conducted for the IAA based on the combined data sets collected throughout the course of investigation.

2.2.4 Rail Yard

Based on the information obtained during the historical investigations at the Rail Yard it was determined that no additional investigation was warranted for that Study Area. Therefore, ARCADIS did not collect any samples at the Rail Yard during the 2008 sampling activities. The site data collected during the historical investigation activities at the Rail Yard are summarized Section 8, along with the findings of human-health and ecological risk assessments for the site.

2.2.5 Western Burning Ground

Extensive sampling activities were conducted at the WBG between 1997 and 2007 to evaluate the effects of historical burning activities at the site. The investigation activities included surface and subsurface soil sampling across the site; sediment and surface water sampling in an adjacent pond and downgradient stream; and also included fish tissue sampling. ARCADIS' review of the historical information indicated that only a few minor data gaps existed, which were primarily related to the pond and downgradient stream. In order to complete the remedial investigation at the WBG, ARCADIS completed the following activities in 2008:

- ARCADIS probed the pond in several areas to evaluate the thickness of the pond sediments; especially in the area where chromium and lead had been detected at concentrations above applicable screening criteria during past sampling events.

- ARCADIS collected co-located sediment and surface water samples from the area of the pond where lead had been detected at concentrations above applicable screening criteria during previous sampling events. These samples were collected to further evaluate lead concentrations within this area and to determine if lead in sediment was affecting surface water quality. The sediment and surface water samples were analyzed for lead by USEPA Method 6010.

- In accordance with the work plan, ARCADIS had planned to conduct vertical profiling samples of the pond sediments to evaluate the vertical distribution of lead within the sediment column. The samples were to be collected at one-foot (ft) depth intervals from four locations in the pond. This sampling was not performed because the probing activities concluded that the pond sediments were generally only 1-ft deep.

- Two co-located sediment and surface water samples were collected from the stream downgradient of the WBG pond to evaluate the presence of PAHs in the stream sediments. Several PAHs had been detected at concentrations above applicable screening levels in one stream sample during a 2002 sampling event. The sample locations were selected to evaluate if PAH concentrations in downstream samples were higher than in upstream samples, which may demonstrate that the PAHs could be attributed to sources other than the WBG (i.e., roads and railroad tracks). The sediment and surface water samples were analyzed for PAHs by USEPA Method 8270.

A complete summary of the samples collected at the WBG during the 2008 investigation is included within the historical sampling matrix presented in Table 2-5. Further details on ARCADIS' investigation activities are presented in Section 9 of this report, along with the findings of the historical investigations conducted at the WBG. Section 9 of this report also presents a summary of the human-health and ecological risk assessments that were conducted for the WBG based on the combined data sets collected throughout the course of investigation.

2.2.6 Facility-Wide Groundwater

During the 2007 groundwater sampling event, several inorganics were detected in three monitoring wells at concentrations above applicable screening criteria. In order to further evaluate inorganics concentrations in groundwater and to provide further insight into overall groundwater quality at the RFAAP-NRU, ARCADIS completed the following activities in 2008.

- ARCADIS collected samples from all eleven groundwater monitoring wells at the site to re-evaluate the inorganics concentrations present in groundwater. Several inorganics had been detected in groundwater samples collected during the 2007 sampling event and the concentrations at some of the monitoring wells were above tap water screening levels. As inorganics are known to be naturally occurring in soils and rock at the RFAAP-NRU it was theorized that the presence of inorganics in the groundwater samples may be attributed to the presence of suspended solids in the groundwater samples left over from the well installation activities. Therefore, ARCADIS utilized low-flow groundwater sampling techniques with an electric submersible pump in an effort to minimize the presence of suspended solids in the samples. All of the collected groundwater samples were submitted for laboratory analysis of total TAL metals by USEPA Method 6010. Samples were also submitted for dissolved TAL metals analysis (laboratory filtered samples) by USEPA Method 6010 for monitoring well samples that had turbidity levels greater than 10 nephelometric turbidity units (NTUs) despite the low flow sampling technique.

- In addition to the monitoring well sampling activities, ARCADIS collected grab samples from four springs located throughout the RFAAP-NRU facility. One of the springs (Wiggins Spring) was located at the head waters of the pond at the WBG, one spring was at the head waters of the pond near the RY, and the other two springs were located in the northeastern portion of the facility. The springs were sampled because they provide an excellent indicator of shallow groundwater quality due to their function as groundwater collectors for relatively large areas. The spring samples were analyzed for inorganics by USEPA Method 6010 and PAHs by USEPA Method 8270.

- In accordance with the work plan, ARCADIS attempted to install one monitoring well in the open area downgradient of the BDDT, near the unnamed stream that runs through the southern portion of the RFAAP-NRU. This well was to be installed to evaluate potential effects to groundwater from the BDDT. ARCADIS completed two borings utilizing air rotary drilling technique in this area in October 2008; one boring was completed to a depth of 75 ft bgs, the other to a depth of 50 ft bgs. Bedrock was encountered at 5 ft bgs in both boreholes. Groundwater was not encountered in either borehole; therefore, the monitoring well installation activities were discontinued. Both boreholes were abandoned with neat cement.

2.3 ARCADIS Groundwater Investigation 2010

At the request of VDEQ, a third round of groundwater samples was collected from the RFAAP-NRU monitoring well network in April 2010 to further refine the understanding of potential groundwater impacts. During the April 2010 groundwater sampling event, ARCADIS performed the following:

- ARCADIS collected samples from all eleven groundwater monitoring wells at the site to re-evaluate the presence of the following within groundwater: VOCs, PAHs, PCBs, explosives, dioxins/furans, total metals, and dissolved metals. Groundwater samples were collected using low-flow sampling techniques in an effort to minimize the presence of suspended solids in the samples.

- In addition to the monitoring well sampling activities, ARCADIS collected grab samples from each of the four springs located throughout the RFAAP-NRU facility (as discussed in Section 2.2.6). The spring samples were analyzed for the following: VOCs, PAHs, PCBs, explosives, and metals

A complete summary of the samples collected during the 2008 and 2010 facility-wide groundwater investigations is included within the historical sampling matrix presented in Table 2-6. Further details on ARCADIS' groundwater investigation activities are presented in Section 10 of this report, along with the findings of the 2007 groundwater investigation. Section 10 of this report also presents a summary of the human-health and ecological risk assessments that were conducted for groundwater based on the combined data sets collected throughout the course of investigation.

3. Environmental Setting and Conceptual Site Model

This section provides a brief discussion of the environmental setting at the RFAAP-NRU and presents the framework of the conceptual site model (CSM) that has guided the environmental investigations and risk assessment activities at the facility. The CSM provides a general overview of the potential contaminant sources, affected media and transport mechanisms, and exposure/receptor scenarios present at the RFAAP-NRU Study Areas. CSMs specific to the various Study Areas at the RFAAP-NRU are presented in Sections 5 through 10 of this report. The following sections present the various components of the general CSM.

3.1 General Site Conditions

The RFAAP-NRU facility is located in the mountains of southwestern Virginia in the Great Valley subprovince of the Valley and Ridge Physiographic Province. The RFAAP-NRU encompasses approximately 2,813 acres of Pulaski County, Virginia, near the town of Dublin (Figure 1-1). Active manufacturing operations at the facility ended in 1945, at the completion of WWII. The RFAAP-NRU currently serves as a storage facility for operations at the MMA. The storage facilities consist of bunker type buildings that are primarily located throughout the eastern portion of the RFAAP-NRU. Paved surface roads run throughout the facility to provide access to the storage bunkers and areas utilized during historical operations at the site. Rail road tracks and spurs are also located in the area of the site identified as the RY.

Despite the historical manufacturing operations that took place at the RFAAP-NRU, and its current use as a storage facility for the MMA, the majority of the land area consists of undeveloped grasslands, heavily forested areas, and agricultural tracts. A portion of the property has recently been converted for use as a military cemetery. The two areas utilized during the historical manufacturing operations, now identified as the BLA and the IAA, are reverting back to more natural conditions as trees, shrubs, and grasses have grown in the open areas of these sites. The BLA and IAA, along with the other Study Areas (BDDT, NBG, RY, and WBG) are all located in the western half of the RFAAP-NRU facility and encompass a small percentage of the total land area at the RFAAP-NRU. An aerial photograph illustrating the layout of the site is presented in Figure 1-2.

With the exception of the storage bunkers and a few maintenance/support buildings, very few active structures remain at the RFAAP-NRU. The buildings at the BLA and the IAA that were utilized during the historical manufacturing operations at the site have been largely dismantled. The wooden roofs and walls that were a part of the BLA and IAA buildings have all been removed for fire safety reasons, leaving only concrete foundations and concrete blast walls. Several open transfer platforms also remain in the RY area.

3.2 Climate

The climate of the region encompassing the RFAAP-NRU is classified as "moderate continental," and is characterized by moderately mild winters and warm summers. Prevailing winds are from the southwest, with an average yearly wind speed between 8 and 10 miles per hour (SCS 1985). Average monthly temperatures range from 29.6°F in January to 72°F in July, with an annual average temperature of about 52°F. Average monthly precipitation ranges from about 2.5 inches to 4.1 inches with an annual total precipitation between 36.9 inches and 41.5 inches (Virginia State Climatological Office 1995). Lake evaporation was measured at 32 inches per year in the same area. Potential evapotranspiration has been calculated at 30 inches/year using the Thornthwaite method (Parsons 1996). Based on these data, the net precipitation in the vicinity of RFAAP ranges between 6.9 inches and 11.5 inches annually. Snowfall in the vicinity of RFAAP averages 17 inches annually. Montgomery and Pulaski Counties lie in one of the areas of highest occurrence of dense fog in the United States. Dense fog can be expected to occur between 20 and 45 days per year.

3.3 Physiography, Geology, and Hydrogeology

3.3.1 Regional Setting

The RFAAP-NRU occupies rolling, somewhat hummocky terrain, underlain by karst carbonate bedrock. The installation lies in the New River Valley, a portion of the 700-mile-long Great Valley, which forms the eastern edge of the Valley and Ridge physiographic province. Like much of the Great Valley, the New River Valley forms a broad, relatively flat low land on the boundary between two mountain systems – Valley and Ridge to the north and the Blue Ridge to the south. The RFAAP-NRU is approximately 5 miles southeast of the foot of the first ridge of the Valley and Ridge (locally, Cloydes Mountain), and about 11 miles northwest of boundary with the Blue Ridge Terrain.

The New River drains the New River Valley, flowing in a meandering course from northwestern North Carolina. The river turns northward near the town of Radford, Virginia, passing through a water gap between Cloydes and Brush Mountains before flowing on northward to the Ohio River. The New River, being the primary drainage channel for the area, drives basin-scale surface water and groundwater flow patterns. At its closest approach, the New River is located approximately 2 miles south of the RFAAP-NRU installation boundary. This portion of the river forms Claytor Lake, which is a 21-mile long reservoir created by Claytor Dam. As a result of the dam, the water level in the lake is approximately 100-ft above the natural river channel. The water level in the New River downstream of Claytor Dam (east of the RFAAP-NRU installation boundary) is approximately 115-ft lower than the water level in Claytor Lake. The river runs in its natural channel downstream of the dam; thus, the water levels in this section of the river likely have a stronger control on regional groundwater flow patterns than the elevation in Claytor Lake. The following table presents a summary of the elevation controls:

Summary of Groundwater Elevation Controls

Location	Approximate Elevation (ft AMSL)
Range of site grade at NRU	1,975 to 2,100
Claytor Lake (2 miles south)	1,845
New River below Claytor Dam (approximately 2.5 miles east)	1,730
Range of groundwater elevations observed at NRU	1,930 to 2,080

3.3.2 Geology

The RFAAP-NRU is underlain by carbonate bedrock of the Cambrian aged Conococheague Formation, overlain by a variably thick veneer of unconsolidated residuum (Virginia Department of Mines, Minerals, and Energy, 2003). A general description of the characteristics of the regional geologic units is presented in the table below:

General Characteristics of RFAAP-NRU Regional Geologic Units

Unit	Characteristics	Thickness
Residuum	The insoluble residual material resulting from dissolution of the Conococheague Fm. Dominantly clay and silt, with occasional sand or gravel components, typically floating.	Highly variable. Zero thickness in many places (i.e., outcrops are common throughout the RFAAP-NRU). Depth to bedrock is most commonly shallow (e.g., 10 ft or less in the RY, BDDT and WBG), but ranges up to 55 ft in the NBG.
Conococheague Fm	Principally blue-gray limestone and dolomite, with occasional thin beds of sandstone, siltstone, shale. The unit is faulted, structurally complex, and karst weathered.	Unknown regionally, but inferred to be many hundreds of feet. Known to be as thick as 2,200 ft in northern Virginia, and 1,700 ft to the southwest, near Abingdon.

(Sources: Site boring data; VDMME, 2003)

Bedrock at the RFAAP-NRU is structurally complex, with at least one major thrust fault trending northeast through the installation. Lesser subsidiary and conjugate faults are inferred to be present at the site, most commonly with a southeast strike. The northeast and southeast structural alignment within the bedrock complex appears to strongly influence surface morphology in terms of stream, mountain, and valley trends, and/or alignments of sinkholes (VDMME, 2003; N. Simmons, 2008). Boring data and outcrop exposures demonstrate that the hummocky terrain of the RFAAP-NRU is bedrock controlled, reflecting both structural controls and differential solution weathering of the bedrock surface.

Bedrock at the RFAAP-NRU and surrounding area consists of a mature karst system (N. Simmons, 2008). Preferential solution weathering of the rock has generated conduit-scale solution porosity, or interconnected networks of solution cavities through which groundwater may move at rates analogous to surface streams. The karst conduit networks are similar to rivers – minor tributary conduits connect to successively larger primary conduits, ultimately converging to the master conduit, which discharges to land surface at springs. Karst features may include sinkholes, caves, and active springs.

The bedrock surface is expected to be pinnacled and grooved, causing the depth to bedrock to vary significantly over short distances. The vertical zone of pinnacles and grooves is interpreted as an epikarst, a complex zone that may variably store shallow perched water or provide rapid infiltration to deeper flow systems (Klimchouk 2004)

A conceptual representation of the geology at the RFAAP-NRU is presented within the hydrogeologic conceptual model (Figure 3-1).

3.3.3 Soil Types

Detailed descriptions of the soil types encountered at the RFAAP-NRU are presented in the *Facility-Wide Background Study Report* (IT 2001) and the *Master Work Plan* (URS 2003). The *Facility-Wide Background Study Report* also provides a summary of the naturally occurring/background inorganic constituent concentrations that can be expected at the RFAAP. The background inorganic constituent concentrations are based on calculated 95 percent Upper Tolerance Limits (95% UTLs) generated from a facility-wide data set that incorporates both surface and subsurface soil from the RFAAP-MMA and the RFAAP-NRU. The background inorganic constituent concentrations are discussed in further detail in Section 4-1.

3.3.4 Hydrogeology

The presence and flow of groundwater in the RFAAP-NRU are governed by several factors:

- Karst solution porosity dominates the facility-wide and valley-scale groundwater system. The very high transmissivity of the bedrock aquifer (imparted by solution porosity) appears to keep regional-scale aquifer groundwater elevations deep, with heads largely controlled by the location and elevation of base-level discharges on the New River or its low-elevation tributaries..

- Lithologic controls influence the vertical interconnections of solution porosity. Contrasts in lithology (likely the presence of insoluble beds) provide localized aquitards that restrict or actually separate flow vertically. This control explains the presence of shallow (potentially perched) groundwater and high-elevation springs in the northern portion of the RFAAP-NRU.

- Structural controls influence the geometry and interconnections of solution porosity. The major fault mapped by VDMME (2003) trending northeast across the RFAAP-NRU truncates the shallow flow system present on the north side the RFAAP-NRU. The fault trace corresponds with a dramatic change in the shallow potentiometric surface. For example, the head in well IAAM-04, located immediately south of the fault, is approximately 60-ft less than the head at IAAM-03, on the north side of the fault. A block diagram depicting the hydrogeologic conceptual model for the site is presented in Figure 3-1 that illustrates the location of the fault.

- Alignments of sinkholes and stream valleys with fault and bedding trends implies that the karst solution is biased by structural planes of weakness in the bedrock (N. Simmons, 2008).
- Low permeability surface soil (the clay-rich residuum) appears to inhibit diffuse groundwater recharge. Recharge is concentrated in sinkholes, where flow through the residuum is short-circuited.

In general terms, groundwater flow in karst systems occurs in convergent conduit networks that are similar in configuration to the tributary systems in streams. Infiltration enters the karst system through sinkholes, when the residuum is clay-rich like at the NRU, and flow through successively larger conduits as flow is contributed from the tributary network. Groundwater flow in karst systems is governed by the base-elevation of discharge points such as springs and the geometry of the conduit networks. From a conceptual perspective, the conduit networks act as collector systems for the groundwater and the springs provide monitoring points that integrate flow across the system.

As discussed in Section 10 of this report, a network of 11 groundwater monitoring wells was installed at the RFAAP-NRU in 2007. Four wells are located in the vicinity of the IAA (IAAMW01 through IAAMW04), three are at the WBG (WBGMW01 through WBGMW03), two at the BLA (BLAMW01 and BLAMW02). Two wells are also located at the NBG (NBGMW01 and NBGMW02). The locations of the monitor wells are depicted in Figure 3-2. The monitor well construction details and depth-to-water measurements from investigation activities completed in 2007 and 2008 are presented in Table 3-1. Groundwater level measurements have indicated that depth-to-water can vary greatly between the monitoring well locations; ranging from 13 ft bgs (WBGMW01) to 150 ft bgs (BLAMW01), and spanning an elevation difference of 150-ft. In general, hydraulic heads indicate an extreme downward gradient. For example, between the two wells in the BLA, screened 53-ft apart vertically, the head difference is 30-ft or more, with the lower head in the deeper well. The magnitude of observed head differences is indicative of poor hydraulic communication and limited groundwater flux occurring vertically across low permeability. These low permeability beds act as semi-confining or perching beds within the aquifer and likely cause groundwater to flow in the same plane as the layer until a discharge point (spring or seep), or until reaching a structural weakness within the layer that forms a vertical migration pathway.

Four springs have been identified at the RFAAP-NRU. These include Wiggins Spring, which is at the head of a pond near the WBG; an unnamed spring at the head of the pond near the WBG; and two unnamed springs in the northeastern portion of the facility (see Figures 3-1 and 3-2). These springs appear to drain a shallow groundwater system in bedrock and/or the epikarst. The elevation of the springs is comparable to shallow groundwater elevations in the NBG, IAA and WBG, which suggests that the springs discharge groundwater only from a shallow flow system, most likely local recharge occurring within the northern portions of the facility.

Though sporadically saturated, the unconsolidated residuum is not interpreted to be a distinct, laterally-extensive aquifer. Site data suggest that saturation within the overburden is localized in bedrock depressions where it functions as storage for flow occurring in the epikarst. Water-level elevation changes of 15 to 20 ft between the 2007 and 2008 measurement rounds at some of the shallower wells in the IAA and WBG, are indicative of a low-storage, slow-draining epikarst.

South of the un-named fault trace, groundwater elevations appear to drop off precipitously (on the order of 100 ft). This suggests that the fault restricts flow across the fault scarp, and effectively restricts/acts as a barrier to the shallow flow systems within the northern fault block. This function of the fault likely explains why the line of springs in the NRU are oriented parallel to the fault trace.

The streams in the NRU (the unnamed stream and Hazel Hollow Creek) are supported by baseflow from spring discharge and are clearly gaining in the northern and western portions of the RFAAP-NRU. After traversing the fault trace, the streams become losing. At the BDDT, a boring completed to approximately 70 ft below the water level in the unnamed creek was dry. This suggests that the unnamed creek is perched in this reach, prevented from drying up or losing significant flow by the low permeability of the clay-rich residuum underlying the stream bed. Infiltration occurring south of the fault trace is expected to recharge a deeper flow system, and will not discharge to surface water within the RFAAP-NRU boundaries.

3.3.5 Groundwater Recharge

The low permeability, clay-rich residuum that overlies inhibits diffuse recharge. Surface runoff is channeled to surface streams or, in some cases, to sinkholes.

Sinkholes and closed depressions are common in the vicinity and occur within the RFAAP-NRU, but are infrequent in the western portion of the facility. The structural and stratigraphic controls that promote the shallow groundwater system in the northwest portion of the RFAAP-NRU are interpreted to also inhibit major sinkhole formation. The following general conditions apply to groundwater recharge at the RFAAP-NRU:

- Infiltration that occurs in the northern portion of the RFAAP-NRU (i.e., north of the fault trace) is expected to be captured in the shallow aquifer system. This system appears to discharge to the shallow springs, wetlands and gaining reaches of the unnamed creek that flows through the southwest portion of the facility, and Hazel Hollow Creek north of the fault trace. A component of flow in this system likely leaks vertically downward into deeper flow systems.

Infiltration that occurs south of the fault trace is expected to recharge directly to deeper flow systems that discharge at springs located outside the boundaries of the installation.

3.4 Surface Water Hydrology

Surface water run-off at the RFAAP-NRU is largely controlled by drainage ditches that parallel the site roads. These drainage ditches, which remain dry except during heavy rainfall events, generally direct run-off toward two small stream networks, or tributaries thereof, located within the RFAAP-NRU. The two stream networks, shown in Figures 3-1 and 3-2, include the following.

- A small, unnamed, creek that flows through the southwestern potion of the facility drains the western portion of the RFAAP-NRU where the Study Areas discussed in this report are located. This stream, referred to as the unnamed creek throughout this report, is largely sourced from two small springs located within the facility. Wiggins Spring is the larger of the two springs and is located at the head waters of a pond at the WBG. The second spring is located at the headwaters of a pond at the RY. A component of flow in the unnamed creek originates from tributaries flowing from offsite to the west. After exiting the RFAAP-NRU, the creek flows to the south and enters Claytor Lake.

- Hazel Hollow Creek emerges in the eastern portion of the RFAAP-NRU from two unnamed springs and a wetland complex. This creek exits the RFAAP-NRU along the eastern boundary of the installation and continues to flow east to the New River, below the Claytor Lake dam.

Three small ponds are located within the boundaries of the RFAAP-NRU. The ponds are all located immediately downgradient of the springs discussed above, and were man-made by damming tributaries of the unnamed creek and Hazel Hollow Creek. The largest of these ponds is located at the Western Burning Ground and is fed by Wiggins Spring. This pond was constructed in the early 1990's.

3.5 Potential Contaminant Sources

Review of the historical land uses and site conditions at the RFAAP-NRU have identified several potential sources that could have contributed to the release of contaminants to environmental media at the site. These potential sources include building materials, electrical transformers, historical manufacturing operations, product/waste spills or leaks, burning operations, and road materials (i.e., tar). It is also possible that off site sources could have been transported to the site through precipitation, smoke deposition, surface water runoff or streams, and groundwater migration. All of these potential sources are considered above ground sources; there are no known burial sites or below ground sources present at the facility.

3.6 Potentially Affected Media and Transport Mechanisms

Potentially affected media at the RFAAP-NRU include surface soils, subsurface soils, sediments, surface water, and groundwater. As such, the site investigations at the RFAAP-NRU have been structured to characterize and delineate potential effects in each of these media.

3.6.1 Surface Soil

Considering that the potential contaminant sources at the RFAAP-NRU Study Areas are all above ground, surface soils located within, or in the immediate vicinity of, a source area would be the media most likely to exhibit effects from historical operations or materials at the site. Surface soils outside of the immediate vicinity of a source area would also have the potential to exhibit effects due to the migration of soils or affected media from the source area. The most common factor affecting surface soil migration would be erosion due to surface water runoff in areas with significant topographic relief. Prior to the completion of the 1998 site restoration activities at the BDDT, erosion in the drainage ditch is known to have transported PAH affected surface soils to a downgradient area. Based on limited topographic relief within the BLA, IAA, RY, and WBG, and the findings of comprehensive soil sampling programs, erosion does not appear to have provided a significant transport mechanism at these Study Area.

Mechanical mixing of soils during grading activities could also have contributed to migration of affected surface soils. Grading activities are known to have taken place in the Western Burning Ground during the course of site operations and when the adjacent pond was constructed in the 1990s. Based on the findings of the investigation activities at the RFAAP-NRU the identified constituents of potential concern (COPCs) generally do not appear to be laterally extensive, which indicates that contaminant migration in surface soils is limited.

3.6.2 Subsurface Soil

While there are no known subsurface source areas at the RFAAP-NRU, subsurface soils would have the potential to exhibit effects as a result of contaminant infiltration or physical mixing with surface soils. However, based on the sampling activities conducted within the various Study Areas at the RFAAP-NRU, the identified COPCs are generally confined to surface soils or shallow subsurface soil samples. This indicates that vertical migration of COPCs is limited at the NRU, which is consistent with the hydrogeologic CSM conclusions that infiltration is limited.

3.6.3 Sediments

Sediments are present within the various creeks, ponds, and drainage ditches located throughout the RFAAP-NRU. Sediments in the creeks, ponds, and drainage ditches have the potential to exhibit effects resulting from the erosion of surface soils and COPCs carried by surface water runoff. Sediments also have the potential to exhibit effects resulting from contaminants present in surface water. Sediments in the ponds would not be expected to be very mobile due to low velocity water movement. Sediments in the streams and drainage ditches are expected to be more mobile due to higher velocity water movement that would have the potential to carry sediments and COPCs downstream. Sampling conducted at the various RFAAP-NRU sites has indicated the presence of COPCs in sediments during isolated sampling events at the BDDT, BLA, IAA, RY, and WBG. Sampling conducted in 2002 has also indicated the presence of COPCs in sediment samples collected from the unnamed creek that flows through the southwest corner of the RFAAP-NRU, upstream of the RFAAP-NRU facility boundary. This indicates sediments affected by off-site and/or upstream sources could be carried onto the site. Potential upstream sources include residential and agricultural properties as well as commercial/industrial areas in the town of Dublin, Virginia.

3.6.4 Surface Water

There are two stream networks within the boundaries of the RFAAP-NRU. One of these streams, which is unnamed, flows through the southwestern portion of the facility and is fed by several small tributaries sourced within the facility boundaries. The other stream network is located in the northeastern portion of the facility and includes Hazel Hollow Creek, and tributaries thereof. There are also small ponds located at the WBG, RY, and in the northeastern portion of the RFAAP-NRU, which were formed by damming spring fed tributaries of the two creeks. The drainage ditches at the RFAAP-NRU carry surface water during heavy rainfall events and are not identified as surface water bodies.

The unnamed creek in the southwest portion of the RFAAP-NRU, and its tributaries, flows in the vicinity of several of the Study Areas, including the BDDT, BLA, RY, and WBG. As such, the creek has the potential to exhibit effects resulting from surface water runoff and sediments transported from these areas. The ponds at the RY and the WBG would also have the potential to exhibit effects resulting from those Study Areas. The unnamed creek also has the potential to carry constituents onto the facility from the upstream sources discussed in Section 3.6.3.

3.6.5 Groundwater

The COPCs that have been identified in soil at each of the Study Areas at the RFAAP-NRU are generally restricted to shallow soils and have not undergone significant lateral transport in solution, as confirmed by comprehensive soil sampling programs. Based on the hydrogeologic conceptual model for the RFAAP-NRU the potential for adverse effects to groundwater are minimal for the following reasons:

- Diffuse infiltration is not a significant pathway in the various Study Areas because of the low permeability of the clay rich soils.

- In the karst setting at the NRU, infiltration of dissolved-phase COCs would occur primarily through sinkholes. However, no evidence exists to suggest that a sinkhole pathway exists for any of the RFAAP-NRU areas under investigation.

The function of the springs as shallow groundwater collectors at the RFAAP-NRU makes them ideal locations for screening for potential groundwater quality issues, as discussed in Section 3.3.4,. As such, the four springs identified at the site were included in the 2008 and 2010 groundwater sampling programs.

3.7 Exposure Pathways

The evaluation of potential exposure scenarios under both current and potential future land use scenarios is an important component of the CSM because it provides the framework for conducting the human-health and ecological risk assessments. Exposure points are locations or “points” where exposure could potentially occur, and exposure routes include the basic pathways through which constituents detected onsite may potentially be taken up by the receptor. Within this RI report, both human and ecological exposure scenarios will be evaluated based on all available data.

3.7.1 Human Exposure

The potentially exposed receptors at the site have been identified based on both current and reasonably anticipated future land use of the areas located in the vicinity of the site. As discussed in Section 3.1, the site is currently utilized as a storage facility for operations at the RFAAP-MMA. There are no active manufacturing operations taking place and there are no residents at the site. Depth to groundwater ranges from 13 ft bgs to more than 150 ft bgs, and groundwater in the vicinity of the site is not being used as a potable water source.

Based on site characteristics discussed above, the current receptors only include a site commercial/industrial worker.

Due to the industrialized/military nature of the site, redevelopment of the site for residential purposes is highly unlikely. Remedial decisions will be based on the current and reasonably expected future use (military industrial). However, hypothetical exposure of residential receptors was evaluated in the risk assessment as a conservative measure and to assist the Army in making risk management decisions. Exposure pathways in the future could potentially include exposure to surface and subsurface soil, sediment, surface water, and groundwater used as a potable water source. Exposure to soil for the residential receptor could occur through ingestion; dermal contact; and inhalation of vapors, asbestos fibers, and/or COPCs adhered to fugitive dust. Exposure to sediment for the resident receptor could occur through ingestion and dermal contact during wading. Exposure to surface water could occur through ingestion or dermal contact during wading while exposure to groundwater could occur though all routes if groundwater is used as a domestic water supply. Further, resident receptors may also be exposed to constituents that might have accumulated in fish tissue samples collected from the unnamed pond in the WBG.

In the event of site redevelopment, construction workers may, in the future, be exposed to surface and subsurface soil if excavation activities take place.

Exposures of hypothetical current or future trespassers were not evaluated because their exposures, if any, would be of a limited frequency and duration since the site is completely fenced and access is controlled. This hypothetical receptor would have far less exposure than the receptors selected for quantitative evaluation (e.g., exposure duration of five days per year for a trespasser versus 250 days per year for the industrial site worker or 350 days per year for a residential scenario).

Likewise, exposure of hypothetical current or future angler receptors from ingestion of fish from the unnamed pond at the WBG was not evaluated because the exposure, if any, would be of a limited frequency and duration since the RFAAP-NRU is completely fenced and access is controlled. In addition, a hypothetical angler receptor would have far less exposure than the resident angler selected for quantitative evaluation.

The potential exposure pathways for human receptors at the RFAAP-NRU are presented in Figure 3-3. The human exposure components of the CSM are discussed in further detail in Appendix A and Section 4.3.3 of this report.

3.7.2 Ecological Exposure

Potential ecological receptors are designated based on the available habitat associated with the site. Terrestrial habitat and aquatic habitat is present at each of the Study Areas. The terrestrial habitat consists of mixed forest, open fields, and grassy areas. The aquatic habitat consists of various storm water drainage channels, creeks, and ponds.

The potentially exposed receptors at the RAAP-NRU include terrestrial wildlife (including mammals, birds, reptiles, and invertebrates), terrestrial plants, and aquatic biota (fish and invertebrates directly within the aquatic habitat). The potential exposure pathways for ecological receptors at the RFAAP-NRU are presented in Figure 3-4. The ecological exposure components of the CSM are discussed in further detail in Appendix A and Section 4.4 of this report.

4. Methods and Procedures for Data Evaluation

This section discusses the methods and procedures that were utilized to evaluate the environmental site conditions at each of the five Study Areas (i.e., BDDT, IAA, BLA, WBG, and RY) and site-wide groundwater at the RFAAP-NRU. Data collected during each phase of investigation were first evaluated by comparison to applicable screening criteria (See Section 4.1). The combined data sets from all investigations were then utilized to develop an assessment of the nature and extent of contamination present at each site. Once the nature and extent of contamination and constituents of potential concern were identified, a site specific HHRA and ERA was conducted for each Study Area and for facility-wide groundwater. The purpose of the risk assessments was to evaluate the potential current and future excess lifetime cancer risks and potential hazards to both human and ecological receptors at the site from exposure to constituents detected in soil, groundwater, surface water, and sediment at the RFAAP-NRU. The risk assessments were conducted in a manner consistent with the approach outlined in the Master Work Plan (URS 2003) in compliance with Comprehensive Environmental Response, Compensation, and Liability Act/ Superfund Amendments and Reauthorization Act (CERCLA/SARA). The results of the data evaluation process and risk assessments for each of the Study Areas and for facility wide groundwater are presented in Sections 5 through 10 of this report.

4.1 Initial Data Comparison Criteria

Environmental data collected from each of the Study Areas are initially discussed by comparison to screening criteria. Comparison criteria are constituent and medium specific concentrations that are used to provide a reference value for site specific analytical data. Comparison criteria are typically published values that are based on calculations which assess the increase in risk under default assumptions to a given population based on the concentrations of constituents in environmental media at a site. These values can be used to assess the risk to a human population or to an ecological population.

The Study Area assessments presented in this report utilize human health based screening levels derived from those presented in the United States Environmental Protection Agency's (USEPA's) Regional Screening Levels (RSLs) table (USEPA 2009a) as comparison criteria. Screening levels for soil and sediment were based on industrial and residential soil RSLs while screening levels for groundwater and surface water were based on tap water RSLs. The RSLs are calculated to demonstrate the concentration of a given constituent that will not result in an increase in risk to an individual beyond a hazard quotient (HQ) of 1 for non-carcinogenic compounds and an increase in cancer risk of 1 x 10^{-6} for potentially carcinogenic compounds. Because the Study Areas presented in this report are potentially contaminated with multiple constituents, and because noncarcinogenic effects can sometimes be cumulative, the RSLs based on noncarcinogenic effects were adjusted to reflect a target HQ of 0.1, where applicable (i.e., the published RSLs for non-carcinogens were divided by 10). For screening levels based on cancer effects where the noncancer screening level was less than 10 times (10x) the cancer level (tagged with c** in RSL table), the non-cancer level was used after adjustment. This adjustment was not conducted for the lead RSLs as they are based on blood lead levels rather than cancer or non-cancer endpoints. Where appropriate, surrogate RSLs were used for constituents that lack screening levels. The adjusted RSLs are referred to as industrial and residential screening levels in this report. Table 4-1 presents a summary of the RSLs utilized during the data comparison process.

It should be noted that there is no RSL available for asbestos. However, it is known that concrete slab floors in some buildings in the BLA and IAA Buildings were covered in a conductive flooring material that contained asbestos. Removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and break away from the underlying concrete. In some cases, the flooring has degraded into a red powder-like material and washed onto the surrounding soils. Since it is known that asbestos is present in some portions of the site, this was carried through as a COPC. However, asbestos is evaluated somewhat differently from other constituents. Thus the general approach used to evaluate it is provided in Section 4.3.4.4.

In addition to the RSLs, inorganic constituents (i.e. inorganics) detected in soil were compared to the background inorganics concentrations presented in the Facility-Wide Background Study Report (IT 2001). The background inorganics concentrations are based on calculated 95% UTLs generated from a facility-wide data set that incorporates both surface and subsurface soil from the RFAAP-MMA and the RFAAP-NRU. The calculated background concentrations are utilized to help differentiate between naturally occurring inorganic concentrations and concentrations resulting from human influence. Inorganics are not considered to be site related contaminants unless the concentrations are above the background concentrations. Table 4-2 presents a summary of the background inorganics concentrations for the RFAAP. As indicated in this table, some of the background inorganics concentrations are higher than the soil RSLs.

4.2 Risk Assessment Data Sets

Samples collected during site investigations conducted from 1997 through 2008 were considered for inclusion in the risk assessment. The environmental data collected throughout the various phases of investigation were grouped by Study Area and medium of interest (e.g., soil, sediment, groundwater and surface water) and then evaluated to produce risk assessment datasets. Soil data were also subdivided into a surface soil for evaluating ecological receptors (0-1 ft), and surface soil (0-2 ft) and combined surface and subsurface soil for evaluating human exposure. The following components were considered in the preparation of the risk assessment datasets: data quality, sample and result type, data qualifications, vertical and spatial distribution of the data, and constituent classification (e.g., dioxins). Each of these considerations is discussed in detail within the comprehensive RFAAP-NRU Risk Assessment presented in Appendix A. Appendix A includes a discussion of the methods and procedures utilized during the risk assessment activities, as well as the findings of the human health and ecological risk assessments for all of the individual Study Areas discussed in this report.

After the risk assessment datasets were prepared, the data included in each dataset were summarized, statistically analyzed, and then tabulated by highlighting the number of detects, number of samples, frequency of detection (FOD), minimum and maximum detected concentrations, and minimum and maximum detection limits.

4.3 Human Health Risk Assessment Methods and Procedures

The purpose of the HHRA is to evaluate the potential current and future potential risks and hazards to human health associated with constituents detected in surface and subsurface soil, groundwater, sediment and surface water samples collected at the RFAAP-NRU. Methods and parameters used in the HHRA were in compliance with USEPA guidance for risk assessments (USEPA 2004a; 2000a; 1997a; 1992; 1991a; 1989) and are consistent with the approach defined in the Master Work Plan (URS 2003). The HHRA methods are discussed in detail in Appendix A and are briefly summarized in the text below.

4.3.1 Constituent Characterization

This section discusses the methods used to select chemicals of potential concern (COPCs) for the HHRA and the physical and chemical properties of the selected COPCs.

COPCs were identified for each of the Study Areas by comparing maximum detected concentrations to health based screening levels. If the maximum detected concentration was greater than the screening level, the constituent was identified as a COPC and quantitatively evaluated in the HHRA. A full discussion of the derivation of the human health based screening levels used is presented in Section 4.1 and the screening levels are presented in Table 4-1. In addition to the screening levels, inorganic constituents detected in soil and sediment were compared to the background inorganic constituent concentrations established in the Facility-Wide Background Study Report (IT 2001). The background inorganic constituent concentrations are presented in Table 4-2. Constituents present at levels within background ranges were retained as COPCs in the HHRA and potential risks and hazards were quantified. The risks associated with naturally occurring levels of inorganics also were quantified and are discussed in comparison to site related risks as part of the risk characterization consistent with USEPA (2002e) guidance. Constituents selected as COPCs based on human health protection were carried forward into the HHRA.

4.3.2 Toxicity Assessment

Toxicity values for potential non-carcinogenic (reference doses - RfDs) and carcinogenic effects (cancer slope factors - CSFs) were obtained from the following sources in order of priority following USEPA (2003b) guidance:

- USEPA Integrated Risk Information System (IRIS) database (USEPA 2008b);
- USEPA's National Center for Environmental Assessment Provisional Peer-Reviewed Toxicity Values (PPRTVs) as reported in USEPA RSL Tables (USEPA 2009a); and
- USEPA’s Health Effects Assessment Summary Tables (HEAST; USEPA 1997b).

Other sources used included the California Environmental Protection Agency (Cal EPA), the Agency for Toxic Substances and Disease Registry (ATSDR) and the World Health Organization (WHO), as referenced by USEPA (2009a).

In accordance with USEPA guidance (USEPA 2005c), PAHs were evaluated using an age-dependent adjustment factors (ADAFs) for assessing carcinogenic risk associated with early-life exposures. Chemical-specific ADAFs were calculated for the PAHs using the data specific to benzo(a)pyrene and other PAHs.

The USEPA identifies lead as a “probable human carcinogen” based on sufficient animal evidence but inadequate human evidence (USEPA 2007a). However, the USEPA does not recommend evaluating lead cancer risk using a CSF (USEPA 2003c). Instead, lead non-carcinogenic risks (identified as neurological effects) are evaluated by predicting blood-lead concentrations using toxicokinetic modeling. This is because there is a strong correlation between lead exposure and resulting blood lead levels. Thus, toxicity values were not identified for lead and exposure to lead was assessed by estimating blood lead levels.

Toxicity values are presented in Tables A.2-4 through A.2-7 within Appendix A.

4.3.3 Exposure Assessment

The exposure assessment is described in detail in Appendix A. The basic components of the exposure assessment steps are summarized below:

4.3.3.1 Receptors and Exposure Pathways

Exposure pathways were identified in Section 3.5.3.1 based on the site characterization information and the fate and transport properties of the constituents detected onsite to identify likely points where human receptors may come in contact with affected media under current or potential future conditions at the site. The following receptors and potentially complete and significant exposure pathways were identified for quantitative analysis at the site:

Current/Future Onsite Commercial/Industrial Worker Receptor

- Dermal contact with surface soil, sediment, and surface water
- Incidental ingestion of surface soil, sediment, and surface water
- Inhalation of particulates in outdoor air
- Inhalation of volatile COPCs in ambient air (if VOCs are selected as COPCs).

Hypothetical Current/Future Onsite Construction/Utility Worker Receptor

- Dermal contact with surface and subsurface soil
- Incidental ingestion of surface or subsurface soil
- Inhalation of particulates in ambient air during soil intrusive activities
- Inhalation of volatile COPCs in surface and subsurface soil in ambient air (if VOCs are selected as COPCs).

Hypothetical Future Onsite Resident

- Dermal contact with surface and subsurface soil, sediment, and surface water
- Ingestion of surface and subsurface soil, sediment, and surface water
- Inhalation of particulates (from soil) in ambient air during outdoor activities
- Inhalation of volatile COPCs in indoor air (if VOCs are selected as COPCs) either from groundwater use in the home or from vapor migration into the home
- Ingestion of fish caught for recreation (where relevant)
- Ingestion of and dermal contact with groundwater used domestically

4.3.3.2 Exposure Point Concentrations

Exposure point concentrations (EPCs) are representative constituent concentrations that a receptor may contact at an exposure point over the exposure period (USEPA 1989). Ideally, the EPC should be the true average concentration; however, because of the uncertainty associated with estimating the true average concentration based on a limited dataset, the estimated upper confidence level (UCL) on the mean (i.e., a UCL of 95 percent or higher) should be used as the EPC. The maximum concentration can be used as the EPC where the UCL cannot be calculated.

EPCs were calculated for COPCs by medium at each Study Area consistent with guidance as discussed in detail with Appendix A. The surface soil, combined surface and subsurface soil, sediment, surface water, and groundwater EPCs are presented in the Study Area-specific data summary tables discussed in later sections of this report.

4.3.3.3 Exposure Parameters

Exposure parameters are values used to quantify the assumed exposure to COPCs for each receptor. For this HHRA, exposure parameters that represent the reasonable maximum exposure scenario were selected.

The receptor-specific exposure parameters are summarized in Table A.2-10 within Appendix A, and are discussed in detail within Appendix A.

4.3.4 Risk Characterization

The equations used in the risk characterization calculations are presented in Tables A.2-11 through A.2-15 within Appendix A.

Potential risks to human health are evaluated quantitatively by combining calculated exposure levels (i.e., dose) and toxicity data. A distinction is made between non-carcinogenic and carcinogenic endpoints as discussed in the subsections below.

4.3.4.1 Non-carcinogenic Effects – Hazard Quotients and Hazard Indices

Exposure doses are averaged over the expected exposure period to evaluate non-carcinogenic effects. The HQ is the ratio of the estimated exposure dose and the RfD. An HQ greater than 1 indicates that the estimated exposure level for that constituent is greater than the RfD. This ratio does not provide the probability of an adverse effect. Although an HQ of 1 indicates that health effects should not occur, an HQ that is greater than 1 does not imply that health effects will occur, but that health effects are possible.

The sum of the HQs is the hazard index (HI). A limitation with the HI approach is the assumption of dose additivity is applied to compounds that may induce different effects by different mechanisms of action. Consequently, the summing of HIs for a number of compounds that are not expected to induce the same type of effects or that do not act by the same mechanism may overestimate the potential for toxic effects (USEPA 1989). Consistent with USEPA risk assessment guidelines for constituent mixtures, in the event that the total HI for an exposure scenario is greater than 1, it is incumbent on a risk assessor to segregate HQs by target organ/critical effect (USEPA 1989). Therefore, if the calculated HI is greater than 1 as a consequence of summing several HQs for constituents not expected to induce the same type of effects or that do not act by the same mechanism, the HIs may be segregated by effect and mechanism of action to derive separate HIs for each target-organ/critical-effect group (USEPA 1989). Where target organ HIs exceeded one, the constituents of concern contributing to those HIs were identified.

4.3.4.2 Carcinogenic Effects - Excess Lifetime Cancer Risk

The excess lifetime cancer risk (ELCR) is an estimate of the potential increased risk of cancer that results from lifetime exposure, at specified average daily dosages, to COPCs at a site. Estimated doses or intakes for each COPC are averaged over the average lifetime of 70 years. It is assumed that a large dose received over a short period is equivalent to a smaller dose received over a longer period, as long as the total doses are equal. The ELCR is calculated as the product of the exposure dose and the CSF. The use of upper percentile EPC and reasonable maximum exposure

(RME) exposure parameters result in a risk estimate that is considered to be an upper-bound estimate; in other words, the true risk is less than that predicted by the model.

The USEPA considers ELCRs within the target risk range of 10^{-6} to 10^{-4} to be generally acceptable. USEPA (1991b) generally considers remediation of sites with risks less than 1 x 10^{-4} to be unwarranted unless there are ecological affects. Where ELCR exceeded $1x10^{-4}$, the risk drivers were identified.

4.3.4.3 Evaluation of Lead Exposures

Exposure to lead is evaluated differently than the other constituents. Cancer risk and non-cancer hazard quotients are not estimated from exposure to lead because health effects from exposure to lead are better characterized by estimating the amount of lead that may reach the bloodstream following exposure.

Consistent with current USEPA guidance (USEPA 2003c), USEPA's Adult Lead Methodology (ALM) model and USEPA's Integrated Exposure Uptake Biokinetic Model for Lead in Children (IEUBK; USEPA, 2005a) were used to evaluate the potential for adverse health effects from exposure to lead by adults and children, respectively. The models were used to calculate the 95th percentile blood-lead concentrations for each receptor, which were compared to the target blood-lead concentration of 10 micrograms per deciliter (µg/dL). The ALM is used to evaluate exposure of both industrial and hypothetical future adult resident receptors. Appendix A provides a complete discussion of the input parameters used for blood lead level modeling.

Blood lead levels were estimated for the three areas where lead was identified as a COPC in soil or sediment: the IAA, the BLA, and the WBG. The model runs and the result summaries for each Study Area are discussed in the section of the report devoted to those Study Areas.

4.3.4.4 Evaluation of Asbestos Exposure

USEPA has recently developed a recommended framework for evaluating potential risks associated with asbestos in soil. This framework addresses the fact that asbestos concentrations in soil are not always good predictors of the level of exposure and risk that may be experienced by individuals who come into contact with that soil. This is because the potential risk experienced by those individuals is not a function of the concentration in the soil but is instead a function of their potential inhalation of asbestos fibers that may become airborne when and if soil is disturbed.

In recognition of this framework, a different approach was used to evaluate potential risks associated with asbestos in surface soil. This approach involved the calculation of air action levels (AALs) by combining the methodology outlined in USEPA's framework document with some of the scenario-specific exposure parameters discussed above. The AALs were then compared with airborne asbestos concentrations measured during activity-based air sampling, to determine whether asbestos might pose a potential risk to individuals who come into contact with that soil. The specific methodology for calculating the AALs is provided in Section 4.4.5 of Appendix A.

4.3.5 Uncertainties in the Human Health Risk Assessment

The risk estimates presented herein are a conservative estimate of potential risks associated with exposure to constituents detected in soil, groundwater, sediment, and surface water at the RFAAP-NRU. Uncertainty is inherent in the risk assessment process, and a discussion of these uncertainties is presented in Appendix A. Each of the three basic building blocks for risk assessment (monitoring data, exposure scenarios, and toxicity values) contributes uncertainties. Each of the uncertainties is accounted for by using conservative assumptions wherever site-specific data are unavailable so that the overall risk estimates are conservative and therefore any decision based upon the risk estimates would be health-protective.

4.4 Ecological Risk Assessment Methods and Procedures

Site-specific ERAs were conducted at each of the five Study Areas evaluated in this RI. The purpose of the ERAs was to evaluate the potential current and future risks and potential hazards to ecological receptors associated with constituents detected in surface soil, sediment, surface water, and spring water conditions at each of the Study Areas within RFAAP-NRU.

The ERAs were conducted in a manner consistent with USEPA guidance for ecological risk assessment (USEPA 2001a; 2000b; 1997c) and follow the approach in the Master Work Plan (URS 2003). The ERAs are intended to provide a conservative understanding of environmental conditions as they relate to the protection of wildlife populations and communities for risk management decision-making at the RFAAP-NRU.

In accordance with USEPA guidance, the ERAs conducted for the five Study Areas at the RFAAP-NRU are comprised of a SLERA and a baseline ERA (BERA) (USEPA

2000b; 1997c). Appendix A provides detailed information on the methods used in the ERA and they are also briefly described in the following sections. Appendix A also contains the complete ERAs for each of the five Study Areas discussed in this report.

4.4.1 Screening Level Ecological Risk Assessment

A SLERA conservatively estimates potential risks that may affect ecological receptors, including terrestrial and aquatic organisms. The SLERA typically compensates for uncertainty in a precautionary manner, by incorporating numerous conservative assumptions. The outcome of the SLERA is the conclusion that either there is a high probability that ecologically significant risks are not posed to receptors, or further investigation in the form of a BERA is warranted. Consistent with USEPA (1997c) guidance, the SLERA is comprised of the following steps:

- Step 1: Screening-Level Problem Formation,
- Step 1: Screening Level Ecological Effects Evaluation,
- Step 2: Screening Level Exposure Estimate and Risk Calculation, and
- Scientific Management Decision Point (SMDP).

For each of the five Study Areas, a modified SLERA was conducted following the typical steps in a SLERA and also incorporating some steps typically taken later in the BERA, as a BERA was anticipated in each Study Area. Methods used during those steps of the SLERA are described in details in Appendix A and are summarized below.

4.4.1.1 Step 1: Screening-Level Problem Formulation Screening Level Ecological Effects Evaluation

The screening-level problem formulation presents information that is used to develop a CSM that illustrates the potential relationships between stressors, pathways, and receptors such as:

- Environmental Setting,
- Identification of Constituents Detected,
- Description of Constituent Fate and Transport Pathways,
- Description of Constituent Mechanisms of Ecotoxicity,
- Description of Potentially Exposed Receptors,

- Identification of Potentially Complete Exposure Pathways, and
- Selection of Generic Assessment and Measurement Endpoints.

For the RFAAP-NRU, hypothetical assessment endpoints include the following:

- Sustainability of small mammal populations;
- Sustainability of avian populations;
- Sustainability of terrestrial plant communities;
- Sustainability of soil invertebrate communities; and
- Sustainability of aquatic communities (i.e., fish and invertebrates).

Because direct measurement of assessment endpoints is often difficult or impossible, surrogate endpoints called measurement endpoints are used to provide the information necessary to evaluate whether the values associated with the assessment endpoint are being protected. A measurement endpoint is defined as a measurable ecological characteristic and/or response to a stressor (USEPA 1998). HQs typically serve as the measurement endpoints for SLERAs.

4.4.1.2 Step 1: Screening-Level Ecological Effects Evaluation

The screening-level ecological effects evaluation involves the identification of ecological screening levels (ESLs) for each detected constituent detected in each environmental medium at the RFAAP-NRU. ESLs are generally based on effects such as mortality and reproductive impairment, and are assumed to be widely applicable to sites around the United States for screening purposes (USEPA 1997c). Typically in a SLERA, ESLs are gathered from one or two sources leaving constituents without ESLs to be evaluated in the BERA. In this SLERA, ESLs were gathered from several sources during the modified SLERA to preserve effort in the BERA.

The following sources were considered in identifying soil ESLs for the SLERA:

- USEPA Ecological Soil Screening Levels (EcoSSLs) (USEPA 2005b);
- Region 5 Ecological Screening Levels (USEPA 2003e); and
- Oak Ridge National Laboratory (Efroymson et. al. 1997a,b; ORNL).

The following sources were considered in identifying sediment ESLs for the SLERA:

- Region 3 Sediment Screening Levels (USEPA 2008b);
- Oak Ridge National Laboratory (Jones et al. 1997, ORNL);
- Region 5 Sediment Screening Levels (USEPA 2003e); and

- U.S. EPA Assessment and Remediation of Contaminated Sediments Program (ARCS) – used for aluminum ESLs.

The following sources were considered in identifying surface water ESLs for the SLERA:

- Region 3 Fresh Water Screening Levels (USEPA 2008c);
- Oak Ridge National Laboratory (Suter and Tsao 1996, ORNL);
- Region 5 Surface Water Screening Levels (USEPA 2003e); and
- USEPA National Ambient Water Quality Criteria (USEPA 2008e).

Where multiple values were provided by sources, the lowest values were conservatively selected as is appropriate for a SLERA (USEPA 2000b; 1998; 1997c) if they were considered to have equal relevance and technical basis and rationales for selection were discussed.

Further, in this step, constituents that have a tendency to bioaccumulate were also identified if they were designated as such by USEPA Region 3 (USEPA 2008c,d) or are included in the USEPA list of bioaccumulative compounds (USEPA 2000c).

Soil, sediment, and surface water ESLs for constituents detected onsite and their bioaccumulation potential are presented in Table A.2-18 within Appendix A.

4.4.1.3 Step 2: Screening-Level Exposure Estimate and Risk Calculation

The screening-level exposure assessment is comprised of the identification of exposure estimates, risk calculations, and the evaluation of uncertainties (USEPA 2001b; 1997c). These components form the lines of evidence necessary to support the SMDP at the conclusion of the SLERA.

Exposure estimates used for the modified SLERA were the maximum detected concentrations for each constituent (USEPA 2001d; 1997c).

Risks to ecological receptors were calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the “maximum HQ”, is a highly conservative surrogate for the assessment endpoints. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse or significant ecological effects are unlikely (USEPA 1997c). Maximum HQs greater than 1 indicate that further evaluation is warranted to evaluate the potential for adverse ecological effects. Therefore, the constituents with HQs greater than 1 are identified as

Constituents of Potential Ecological Concern (COPECs) and carried forward into Step 3a of the BERA, except where the constituents are inorganics with maximum concentrations that are not greater than background levels. The comparison with background is typically done in the first step of a BERA, however it was done here in the modified SLERA. Constituents were also identified as COPECs if no ESL was available or if it was identified as bioaccumulative.

4.4.1.4 Scientific Management Decision Point

SMDPs represent critical steps in the ecological risk assessment process where risk management decision-making occurs. As was previously stated, the BERA is conducted for constituents with HQs that exceed 1 and constituents that lack ESLs. Reporting occurs after either Step 2 or Step 3a, depending on the results obtained in Step 2, so that additional evaluation of risks can be evaluated if needed and reporting can be streamlined into a single report (USEPA, 2000b). Generally, the following types of decisions are considered at this SMDP:

- Whether the available information is adequate to conclude that ecological risks are negligible and, therefore, there is no need for remediation on the basis of ecological risk.
- Whether the available information is not adequate to make a decision at this point, and the ecological risk assessment process should continue.
- Whether the available information indicates a potential for adverse ecological effects, and a more thorough assessment or remediation is warranted.

The results of the screening-level risk calculations determine if the ERA should continue into the BERA.

4.4.2 Baseline Ecological Risk Assessment

The BERA is designed to more realistically identify the nature and extent of ecological risks to support informed risk management decision-making (USEPA 2000b; 1997c). This approach contrasts with the SLERA, which is designed to conservatively rule out further evaluation of constituents and media that clearly do not pose a significant ecological risk.

Methods and Procedures for Data Evaluation

This section presents Step 3a of the BERA for the RFAAP-NRU, which is a refinement of the Step 2 exposure estimates and risk characterization, and focuses only on COPECs that were not eliminated in the SLERA. The refinement of the assessment presented in Step 1 and Step 2 is necessary to help focus and streamline further risk assessment activities on the constituents that pose the greatest potential risk to ecological receptors (USEPA 2001b; 2000b; 1997c). It is intended as an "incremental iteration of exposure, effects, and risk characterization" (USEPA 2001a). The outcome of this refined screening process is a list of COPECs to be retained for further evaluation in the BERA process.

The Step 3a discussion for the RFAAP-NRU is comprised of the following:

- Refinement of the list of COPECs,
- Refinement of Risk Calculations for Direct Contact COPECs,
- Assessment and Measurements Endpoints for Bioaccumulative COPECs, and
- Uncertainties.

Step 3a is followed by a SMDP that involves the reporting of results of Steps 1 through 3a.

4.4.2.1 Step 3a: Refinement of Constituents of Potential Ecological Concern and Direct Contact Risk Estimates

The list of COPECs was refined in this BERA by refining the HQs. The refined HQs were calculated for the COPECs identified in the SLERA, using refined EPCs (i.e., the lesser of the maximum detected concentration and the UCL) which is consistent with the approach for "incremental iteration of exposure, effects, and risk characterization" (USEPA 2001a; 1997c). Constituents identified as COPECs in the BERA that were bioaccumulative were evaluated using food chain models.

Further, it is well known that sediment toxicity of a substance is related to the bioavailable fraction of that substance in the pore water of sediments. Substances that are sequestered by sediment ligands are neither bioavailable nor toxic to benthic organisms. Organic compounds typically adhere to other organics in sediment such as humic acid. Inorganics can be sequestered by both organic matter in sediment and by sulfides present in the anoxic region of sediment. Risk from organic compounds can be refined by using partitioning techniques- specifically by normalizing the concentration to the amount of organic carbon in sediment then dividing that quotient by a value that represents an acceptable limit to give what is referred to as a Toxic Unit (TU). For whole assess of compounds that might be additive, the summation of the TUs represents the HQ. If the HQ (total TUs) is equal to or less than one in a particular sediment sample, the concentration of the organic mixture in sediment is acceptable for the protection of benthic organisms. If the HQ exceeds one, the concentration of the organic mixture in the sediment may not be acceptable for the protection of benthic organisms.

When PAHs were identified as COPECs, toxic units based on PAH *Equilibrium Partitioning Sediment Benchmarks (ESBs; USEPA 2003g) referred to as* ESBTU were used to refine risk estimates. The ESBTU approach was used to calculate a total TU which was compared to the benchmark of one. Where available, sample specific total organic carbon (TOC) was used otherwise the average TOC at the site was used instead. TOC ranged between 2.2% to 5.4% at the site and averaged at 3.4 percent (Tables 5-7, 6-2, 7-7, 7-8, 9-5, 9-8, 9-10, and 9-11). This approach is discussed in detail in Appendix A.

4.4.2.2 Step 3 a: Assessment and Measurement Endpoints for Bioaccumulative COPECs

Following the identification of bioaccumulative COPECs, the assessment and measurement endpoints at the RAAFP-NRU were refined. Additional assessment and measurement endpoint are summarized in the following table:

Additional Assessment and Measurement Endpoints

Assessment Endpoint	Measurement Endpoint	Effects Measured
Survival and reproductive success of mammals exposed to bioaccumulative compounds in the terrestrial and aquatic food chain	Adverse changes in survival and reproduction as indicated by food chain modeling for short-tailed shrews and mink	NOAELs and LOAELs related to adverse chronic effects, such as reduced survival and reduced litter size
Survival and reproductive success of birds exposed to bioaccumulative compounds in the terrestrial and aquatic food chain	Adverse changes in survival and reproduction as indicated by food chain modeling for American robins and for the Great Blue Heron	NOAELs and LOAELs related to adverse chronic effects, such as eggshell thinning or reduced fledgling survival

NOAEL no observed adverse effect level.

LOAEL lowest observed adverse effect level.

A discussion of the wildlife receptors selected as measurements endpoints at the RAAF-NRU is presented in Appendix A. Wildlife receptor exposure parameters were gathered from USEPA (1993a,b) and from literature sources as applicable. Wildlife receptor exposure parameters are summarized in Table A2-19 within Appendix A.

4.4.2.3 Food chain Modeling

Bioaccumulative COPECs were identified and were assessed using food chain modeling in both the terrestrial and aquatic food chains. Food chain models predict detrimental effects to wildlife survival and reproduction. Food sources for terrestrial model include soil, vegetation, invertebrates and small mammals and food sources for aquatic food chains include sediment, surface water, vegetation, invertebrates, small mammals, and fish. Measured concentrations in the food sources were used where available (i.e., soil, sediment, and surface water in all Study Areas and whole body fish tissue concentrations in the unnamed pond in the WBG). To estimate concentrations in plants, invertebrates and small mammals, and fish, bioconcentration factors (BCFs) and bioaccumulation factors (BAFs) were used. BCFs describe the transfer (uptake) of a constituent from environmental media into tissues of vegetation and organisms in the food chain, while BAFs describe the transfer (uptake) of a constituent from dietary tissue into tissues of organisms in the food chain. The following medium-biota BCFs and BAFs were developed:

- Soil-to-Vegetation Uptake ($BCFsl_v$)
- Soil-to-Invertebrate Uptake ($BCFsl_i$)
- Soil-to-Mammal/Bird Uptake ($BAFsl_{mam}$).
- Sediment-to-Plant Uptake ($BCFsed_{plant;}$ dw)
- Sediment-to-Invertebrate ($BCFsed_{inv}$)
- Sediment-to-Mammal ($BAFsed_{mam}$)
- Sediment-to-Fish ($BAFsed_{fish}$).

The soil and sediment BCFs and BAFs for the COPECs are identified in Tables A.2-20 and A.2-21, within Appendix A, respectively. The tables include the sources where each value was obtained.

4.4.2.3.1 Intake Assessment

Daily intake represents an estimate of a COPEC dose that a receptor might receive on a daily basis, and is calculated by summing intakes for assumed exposure pathways (i.e., dietary composition types) for each receptor. Intake is calculated by combining the concentration of a COPEC in an exposure media (soil/sediment, food, and water) with applicable receptor exposure assumptions. Two types of exposure concentrations were used in the BERA. For the maximum risk estimates, maximum concentrations were used as exposure concentrations while for the refined scenario, EPCs based on the lower of the maximum and the UCL (where calculable) were used as the exposure concentrations.

To estimate the concentration of a bioaccumulative COPEC in a secondary food source (vegetation, invertebrates, small mammals, fish), bioaccumulation factors (BAFs) are used. To estimate intake in the wildlife receptor, the concentrations in the food sources were combined with wildlife receptor exposure parameters.

4.4.2.3.2 Effects Assessment

Food chain modeling requires the use of toxicity reference values (TRVs) to describe the potential toxicity of the COPECs to ecological receptors. The TRV is the assumed safe dose (in milligrams per kilogram body weight per day [mg/kg-BW-day]) to the receptor species. Calculation of TRVs generally relies on the use of laboratory toxicity benchmarks for laboratory species, as data on wildlife species usually are not available. Ecotoxicity benchmarks are typically reported as no observed adverse effect levels (NOAELs) and lowest observed adverse effect levels (LOAELs) for the laboratory species upon which testing was conducted.

For mammalian receptors, NOAELs and LOAELs are adjusted to account for the differences in body weights between the species tested and the receptor species (Sample et al. 1996). The extrapolation is based on the premise that metabolic function and toxicity are related to body size (i.e., constituents are less toxic to smaller animals because they metabolize and excrete constituents faster). Therefore, mammalian toxicity values were derived from toxicity values from laboratory studies using the Sample et al. (1996) equation. Toxicity values for birds are not adjusted to reflect the different weights of test species and wildlife receptor species (Sample et al. 1996).

Avian and mammalian TRVs used in this BERA are presented in Tables A.2-22 and A.2-23, within Appendix A, respectively.

4.4.2.4 Risk Characterization

Potential risk was estimated using HQs, which were the ratio of the concentration in a given media to the screening level in the media. For the assessment endpoint on higher trophic levels, the HQ was the ratio of the daily intake to the TRV. Equations used for risk characterization including intake equations and equation used to estimate mammalian and avian TRVs are presented in Table A.2-24.

Maximum risk estimates were calculated by combining maximum concentrations and conservative (maximum) exposure assumptions in the food chain models. Refined risk estimates were calculated by combining EPCs, based on the UCL where calculable and maximum concentrations if not, and screening levels or refined exposure assumptions in the food chain models.

4.4.2.5 Refined Uncertainties

A BERA is designed to evaluate potential risks for wildlife by incorporating iterative changes that reduce uncertainty (when possible) and provides more realistic exposure assumptions. Uncertainties associated with the BERA are summarized on Table A.2-18 within Appendix A.

4.4.2.6 Scientific Management Decision Point

As discussed previously, the SMDP represents a critical step in the ecological risk assessment process where risk management decision-making occurs (Figures 4-1 and 4-2). An SMDP occurs after Step 2 and Step 3a (if necessary based on the results of Step 2), so that additional evaluation of risks can be conducted if needed and reporting can be streamlined into a single report (USEPA 2000b). Generally, the following types of decisions are considered at this SMDP:

- Whether the available information is adequate to conclude that ecological risks are negligible and, therefore, there is no need for remediation to mitigate ecological risks.

- Whether the available information is not adequate to make a decision at this point, and the ecological risk assessment process should continue.

- Whether the available information indicates a potential for adverse ecological effects, and a more thorough assessment or remediation is warranted.

If the SMDP indicates that either information is not adequate to make a decision or information indicates a potential for adverse ecological effects, then the ERA process should continue.

5. Building Debris Disposal Trench

5.1 Site Description and History

The BDDT is located in the southern portion of the RFAAP-NRU, south of A Avenue (Figure 1-2). The trench was formerly an ephemeral unlined natural drainage channel that had eroded into the clay surficial soil. The trench channels surface water runoff from the surrounding area down the length of the trench towards an unnamed creek which passes through the area at the base of the BDDT. An approximately 600 ft long portion of the natural depression formed by the trench was previously utilized for the disposal of miscellaneous building debris derived from the dismantling of various structures at the RFAAP-NRU. The building debris consisted of concrete, wood, and rusted and broken drums of a black, tarry substance believed to be roofing tar. The building debris and any visibly stained soil were removed from the trench during a 1998 site investigation. The excavated material was replaced with clean fill and the trench was lined with a geotextile fabric and filled with riprap to minimize the potential for erosion. The open area downgradient of the trench did not contain any debris and was not addressed during the 1998 site restoration activities. However, the open area downgradient of the trench is covered with a thick grass groundcover and is a natural depositional area for any soils that would have washed out of the disposal trench prior to the site restoration. An aerial photograph of the BDDT area is included as Figure 5-1 that depicts the layout of the site.

5.2 Physical Setting

Rolling, grass-covered hills with incised drainage channels provide the setting for the BDDT. The trench runs from north to south between two hills and is approximately 650ft long by 15 ft wide. The head of the trench begins at A Avenue, at an approximate elevation of 2,000 ft above mean sea level (amsl) and slopes downward to the south ending an elevation of approximately 1970 ft amsl. The area downgradient of the trench widens into an open area between the two hills before ending at a small unnamed creek that runs through the southern portion of the RFAAP-NRU. The elevation of the creek bed downgradient of the BDDT is approximately 1960 ft amsl.

The surface soils in the BDDT area generally consist of an organic-rich silty-clay approximately 1 ft deep, which is typical of topsoil throughout the vegetated areas of the RFAAP-NRU. A silty-clay layer with a lower organic content, typical of the Carbo Unit, underlies the surface soils. This unit ranges from strong brown to brownish yellow in color and extends to approximately 4 ft bgs. Bedrock is generally encountered around 5.5 ft bgs, with a saprolitic weathering zone extending from 4 ft bgs to refusal at the bedrock surface. The reported depths are approximate, since the bedrock surface is variable and consists of weathered shale interbedded with layers of limestone and dolomite. Bedrock outcrops are visible along the length of the trench.

5.3 Conceptual Site Model

In accordance with the general CSM presented in Section 3.5, potentially affected media at this site include surface and subsurface soil in the disposal trench and the open area downgradient of the trench. Potentially affected media also include sediments and surface water in the downgradient creek. Surface and subsurface soils within the former disposal trench are known to have been affected by the debris that had been placed in the trench. These effects were mitigated by the 1998 site restoration activities. In addition to minimizing the exposure scenarios in the source area, the site restoration activities removed the potential for erosion to carry contaminants to downgradient areas.

While debris has not been detected in areas downgradient of the disposal trench, soils and COPCs from the trench were carried downslope during rainfall events prior to, and during, the restoration activities. The eroded soils collected in the heavily vegetated, open area downgradient of the trench resulting in the presence of COPCs in surface soil within this area. During heavy rainfall events eroded soils and surface water from the disposal area would have reached the unnamed creek at the downgradient reach of the BDDT, with potential effects to sediment and surface water. A heavy rainfall event is known to have occurred during the 1998 site restoration activities that resulted in the detection of PAHs in creek sediments during a subsequent sampling event.

5.4 Environmental Investigations

The BDDT was originally designated a Study Area for the RFAAP-NRU due to the disposal of construction debris in the trench. The debris included deteriorating 55-gallon drums of a black, tarry substance interpreted to be roofing tar. The presence of these drums, and other debris in a surface water drainage pathway warranted an investigation of environmental media, including soil from the trench, soil downgradient of the trench, and surface water/sediment from the unnamed creek at the base of the trench. Environmental investigations at the BDDT have been on-going since 1997 and have included:

Building Debris Disposal Trench

- 1997 – Preliminary Sampling by Alliant Techsystems, Inc. (ATK)
- 1998 – Independent Sampling by Gannett Fleming
- 1998 – Remedial Investigation by ICF Kaiser Engineers, Inc. (ICF KE)
- 2002 – Remedial Investigation by Shaw Environmental, Inc. (Shaw)
- 2004 – Additional Characterization Sampling by Shaw
- 2008 – Remedial Investigation by ARCADIS

The goals and findings of each of these investigations are summarized in the following sections. As discussed in Section 4.1 the constituent detections reported in these sections are compared to their medium specific screening criteria (i.e. 2009 RSLs), where applicable.

5.4.1 Preliminary Sampling, ATK, 1997

The initial investigation at the BDDT was conducted by ATK in October 1997. The investigation was conducted for purpose of characterizing potential effects from the building debris at the site. The following samples were collected during this event:

- One tar sample for Toxicity Characteristic Leachate Procedure (TCLP) SVOCs;
- One surface water sample from the unnamed creek downstream from the confluence with the BDDT for Target Compound List (TCL) SVOCs; and,
- One surface soil sample for TCL SVOCs.

The laboratory analytical results from these samples reportedly indicated that SVOC concentrations from the TCLP tar sample and the surface water sample were below detection limits. However, the results from the soil sample, which was collected directly downslope from a leaking drum, indicated that the following seven compounds were detected at concentrations above industrial RSLs:

- benzo(a)anthracene
- benzo(b)fluoranthene
- benzo(k)fluoranthene
- chrysene
- dibenzo(a,h)anthracene
- indeno(1,2,3-cd)pyrene
- naphthalene

Building Debris Disposal Trench

Two additional PAHs (fluoranthene and pyrene) were detected in the soil sample at concentrations between the residential and industrial RSLs. The analytical results for the soil sample are summarized in Table 5-1. The exact locations of the samples collected during this preliminary sampling event are unknown; therefore, the sample locations are not depicted on any of the figures presented in this report.

5.4.2 Independent Sampling, Gannett Fleming, 1998

Gannett Fleming conducted an independent sampling event in 1998 under the direction of the USEPA to help further characterize the site and to identify potential effects to the unnamed creek downgradient of the BDDT (Shaw 2004b). The following samples were collected during this investigation:

- One downstream surface water sample (SW-07), and
- Three downstream sediment samples (SD-06, SD-07, SD-08).

The surface water and sediment samples were analyzed for TCL VOCs, TCL SVOCs, PCBs, explosives, and TAL inorganics. The laboratory analytical results for these sediment and surface water samples are summarized in Tables 5-2 and 5-3, respectively. The sample locations are depicted in Figure 5-2. The analytical data from this event indicated the following:

TCL VOCs. No VOCs were detected in the sediment or surface water samples.

TCL SVOCs. A total of eleven SVOC/PAH compounds were detected in the sediment samples collected at locations SD-07 and SD-08 (see Table 5-2). The PAH benzo(a)pyrene was detected at a concentration above the industrial RSL in one of the sediment samples (SD08). Benzo(a)anthracene, benzo(b)fluoranthene, and indeno(1,2,3-cd)pyrene were also detected at sample location SD08 at concentrations above residential RSLs. No SVOCs were detected in the surface water sample.

PCBs. No PCBs were detected in the sediment or surface water samples.

Explosives. No explosive constituents were detected in the sediment or surface water samples.

TAL Inorganics. Seventeen inorganic constituents were detected in the sediment samples collected at SD-06, SD-07, and SD-08 (Table 5-2). All of the detected concentrations were below applicable industrial and residential RSLs and/or the

Building Debris Disposal Trench

established facility-wide background concentrations. Five inorganic constituents were detected in the surface water sample collected at SW-07 (see Table 5-3); the reported concentrations were all below applicable tap water RSLs.

5.4.3 Remedial Investigation, ICF KE, 1998

ICF KE conducted an RI at the BDDT in 1998 to further assess effects that disposal activities may have had on the unnamed creek and soil underlying building debris in the trench (Shaw 2004b). Activities completed during this phase of investigation at the site included:

- A geophysical survey to identify buried debris in the disposal trench.
- Removal of debris and stained soils from the disposal trench.
- Collection of 34 soil samples along the length of the disposal trench.
- Collection of 3 soil samples from the area downgradient of the disposal trench.
- Collection of 7 co-located surface water/sediment samples from the unnamed creek.
- Site restoration activities that included the placement of clean fill and rip-rap in the former disposal area.

5.4.3.1 1998 Geophysical Survey

A Geonics EM61 bottom coil geophysical survey was conducted along the length of the disposal trench to locate potentially buried drums and other miscellaneous metallic subsurface debris. The results of the survey were used to guide the collection of subsurface soil samples and indicated that metallic debris was largely limited to the confines of the open disposal trench. The findings of the geophysical survey are summarized in a report entitled *Results of Geophysical Investigation Report* prepared by NAEVA Geophysics, Inc. (NAEVA 1998).

5.4.3.2 1998 Debris and Soil Removal Activities

The construction debris and underlying surface soils were removed from the BDDT during 1998 to allow ICF KE to evaluate the quality of the soil below the debris. The removal activities commenced at the northern end of the trench, approximately 120 ft south of the culvert that passes under A Avenue, and extended approximately 605 ft to the south. Soil and debris that had been removed from the trench were sampled and analyzed for TCLP waste characteristics. The waste characterization sample results

Building Debris Disposal Trench

indicated that the material was non-hazardous; therefore, the debris and soil were segregated and disposed off-site as nonhazardous material. No visible debris remained at the BDDT upon completion of the removal activities.

5.4.3.3 1998 Debris Area Soil Sampling

Upon completion of the debris and soil removal activities, a total of 34 soil samples (DTSB1 through DTSB23 and DTSB35 through DTSB45) were collected along the length of the trench. The samples were collected from the newly excavated trench floor to a depth of 1 ft bgs and were collected at an average spacing of 17.5 ft along the length of the trench. The sample locations were biased towards areas that had contained abundant debris or visibly stained soils. A site map depicting the sample locations is presented as Figure 5-2. All samples were analyzed for TCL VOCs, TCL SVOCs, PAHs, explosives, and TAL inorganics. The laboratory analytical results from this sampling event, which are summarized in Table 5-4, indicated the following:

TCL VOCs. Two VOCs (1,2,3-trichloropropane and methylene chloride) were detected at very low concentrations within a limited number of the soil samples (see Table 5-4). The reported concentrations of these constituents were several orders of magnitude below applicable residential and industrial screening levels.

SVOCs. A total of nine different SVOCs were detected in various debris area soil samples (Table 5-4). The detected concentrations of these constituents were all below applicable industrial and residential RSLs.

PAHs. A total of fifteen different PAH constituents were detected in the debris area soil samples using the PAH specific analytical method. A complete list of the detected constituents and sample specific concentrations is included in Table 5-4. Five of the detected constituents [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene] were present at several sample locations at concentrations above industrial RSLs. Benzo(k)fluoranthene and chrysene were also detected in several samples at concentrations above their respective residential RSLs. The other detected PAH constituents were not detected at concentrations above applicable industrial or residential RSLs.

Explosives. No explosives were detected in the BDDT soil samples (see Table 5-4).

TAL Inorganics. Several TAL inorganics were detected in the soil samples collected from the disposal trench. Aluminum, antimony, arsenic, cobalt, iron, manganese,

Building Debris Disposal Trench

thallium, and vanadium were detected at concentrations above residential or industrial RSLs. However, the detected inorganics concentrations were all below their respective background concentrations developed in the facility-wide background study (IT 2001).

It should be noted that trench sampling locations were reportedly covered with clean fill, a geotextile membrane and riprap upon completion of the site restoration activities.

5.4.3.4 1998 Downgradient Soil Sampling

Three surface soil samples (DTSS1, DTSS2, and DTSS3) were collected from the area downgradient of the disposal trench to assess whether surface soils in this area had been affected by the downgradient transport of constituents from the disposal site. The sample locations are depicted in Figure 5-2 and the laboratory analytical results are presented in Table 5-4. All three samples were analyzed for TCL VOCs, SVOCs/PAHs, explosives, and TAL inorganics. The analytical results indicated the following:

VOCs. Two VOCs (trimethylbenzene and xylene) were detected in two of the three soil samples (see Table 5-4). The detected concentrations were several orders of magnitude below applicable RSLs.

SVOCs. Seventeen PAH constituents were detected in soil samples at DTSS1, DTSS2 and DTSS3 via the SVOC laboratory analyses (see Table 5-4). There were no non-PAH SVOCs detected in the soil samples. Benzo(a)pyrene was detected in each of the three soil samples at concentrations above the industrial RSL. Benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, benzo(k)fluoranthene, and indeno(1,2,3-cd)pyrene were also detected in each of the three samples at concentrations above residential and/or industrial RSLs.

Explosives. No explosives were detected in the soil samples (see Table 5-4).

Inorganics. Several inorganics (i.e., aluminum, arsenic, cobalt, iron, manganese, and vanadium) were detected at concentrations above residential and/or industrial RSLs. However, the majority of the detections were below the established facility-wide background concentrations for the RFAAP-NRU. The only exceptions were cobalt and manganese at sample location DTSS2, both of which were detected at concentrations above the industrial RSLs and slightly above background levels. Iron was also detected at DTSS3 at a concentration above the residential RSL and slightly above established background level.

5.4.3.5 1998 Surface Water and Sediment Sampling

Two rounds of surface water and sediment sampling were conducted during the 1998 ICF KE investigation activities to assess the presence of site related constituents in the unnamed creek downgradient of the BDDT. The first round, completed on July 17, 1998, included the collection of three co-located surface water/sediment samples. One of the sample locations (DTSW/SD3) was located approximately 70 ft upstream of the confluence of the BDDT and the unnamed stream. Sample locations DTSW/SD2 and DTSW/SD1 were located approximately 114 and 223 ft downstream from the confluence and corresponded to the Gannett Fleming sample locations SD-06 and SD-07, respectively.

The second round of sampling, conducted on August 18, 1998, included the collection of four additional co-located surface water/sediment samples following a heavy rainfall event that occurred during the site restoration activities for the disposal trench. During this rainfall event, exposed soils in the disposal trench were washed downgradient into the creek and the open area between the creek and the trench. Samples DTSW/SD1-2, DTSW/SD2-2, and DTSW/SD3-2 were collected from the same locations as the July 1998 surface water/sediment samples. Sample DTSW/SD4 was collected approximately 545 ft downstream from the confluence of the disposal trench area and the creek.

The sediment and surface water samples collected during both the July and August 2008 sampling events were submitted for laboratory analysis of VOCs, SVOCs, PAHs, explosives, and TAL inorganics. The analytical results for the sediment samples are summarized in Table 5-5. The analytical results for the surface water samples are summarized in Table 5-6. The sample locations are depicted in Figure 5-2. The results indicated the following:

VOCs. Bromodichloromethane and chloroform were detected in surface water sample DTSW3 collected in August, 1998 (See Table 5-6). The detected concentrations were above their respective tap water RSLs in this sample, but these constituents were not detected in any of the other surface water samples collected in 1998. Both constituents are common laboratory contaminants and are not believed to be related to the site. No VOCs were detected at concentrations above applicable screening criteria in any of the sediment samples (See Table 5-5).

Building Debris Disposal Trench

PAHs/SVOCs. Chrysene, fluoranthene, phenanthrene, and pyrene were detected in sediment samples collected during both the July and August sediment sampling events (see Table 5-5). However, the detected concentrations of these constituents were below applicable residential RSLs. During the August 1998 sampling event, benzo(a)pyrene was detected in two sediment samples (DTSD01 and DTSD04) at concentrations above the applicable residential RSL. This constituent was not detected in the samples collected at these locations in July 1998, indicating that the rainfall event may have washed PAH contaminated soil into the creek from the disposal area. No other PAHs were detected at concentrations above applicable screening levels in sediment. PAHs were not detected in the surface water samples (See Table 5-6).

Explosives. No explosives were detected in any of the sediment or surface water samples (see Table 5-5).

Inorganics. Several inorganics were detected in the surface water samples collected in 1998 (see Table 5-6); however, thallium was the only inorganic detected at a concentration above of the applicable tap water RSLs. Thallium was detected above the tap water RSL at sample location DTSW2 during both the July and August 1998 sampling events. It was also detected above the tap water RSL at sample location DTSW4 in August 1998. Several inorganics were also detected in all of the sediment samples (see Table 5-5). However, iron and manganese at sample location DTSD03-2 in August 1998, were the only constituents detected above background levels and applicable residential RSLs. These constituents have not been attributed to the disposal activities at the site and are believed to be naturally occurring.

5.4.3.6 1998 Site Restoration Activities

After completion of site sampling activities, the excavated portion of the BDDT was backfilled with clean fill material. A geotextile membrane and riprap was placed over the fill to provide erosion control and prevent soils in the trench with residual PAHs from washing to downgradient areas.

5.4.4 Remedial Investigation, Shaw, 2002

During 2002 Shaw completed remedial investigation activities at the BDDT to further evaluate potential effects to the soils in the open area downgradient of the BDDT and to re-evaluate constituent detections in the unnamed creek (Shaw 2004b). Although there was no evidence of any debris having been disposed in the open area

Building Debris Disposal Trench

downgradient of trench, soils from the trench were known to have washed out of the trench and into this area prior to the 1998 site restoration activities. Activities completed during the 2002 phase of the investigation included:

- Two soil borings (DTSB46 and DTSB47) to evaluate the vertical extent of site related constituents in soil downgradient of the BDDT.
- Six co-located surface water and sediment samples (DTSW/SD05, DTSW/SD06, DTSW/SD07, DTSW/SD08, DTSW/SD09, and DTSW/SD10) from the creek downgradient of the BDDT.

5.4.4.1 2002 Soil Sampling

Soil samples were collected at 0 to 0.5 ft bgs and 1 to 3 ft bgs at sample locations DTSB46 and DTSB 47. The samples were analyzed for VOCs, PAHs, PCBs, pesticides, herbicides, and TAL inorganics. The laboratory analytical results from this sampling event are summarized in Table 5-7 and the sample locations are depicted in Figure 5-2.

VOCs. VOCs were not detected in the surface or subsurface soil samples.

PAHs. A total of seventeen PAHs were detected in the surface and subsurface soil samples (see Table 5-7). However, only six of the detected PAHs [i.e., benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene] were detected at concentrations above industrial screening levels. The concentrations above the industrial screening levels all occurred in the both of the surface soil samples. No constituents were detected at concentrations above the industrial RSL in the two subsurface soil samples. Although, benzo(a)pyrene was detected in one of the subsurface soil samples (DTSB46) at a concentration above the residential RSL.

PCBs. PCBs were not detected in any of the surface or subsurface soil samples (see Table 5-7).

Pesticides. Two pesticides (4,4'-DDD and methoxylchlor) were detected in the surface soil sample at DTSB46 (see Table 5-7). The concentrations of both detected pesticides are approximately three orders of magnitude below residential RSLs.

Building Debris Disposal Trench

Herbicides. Four herbicides were detected in surface soil sample DTSB46 (see Table 5-7). Reported concentrations of three (2,4-D; dalapon; and dicamba) of the four compounds are below the residential RSL. However, MCPP was detected at a concentration of 13.5 mg/kg, which is greater than its residential screening level (6.1 mg/kg), but below the industrial screening level (62 mg/kg).

TAL Inorganics. Several inorganics were detected in both the surface and subsurface soil samples (See Table 5-7); however, the detected concentrations were either below the applicable residential and industrial screening levels or the facility-wide background inorganics concentrations.

5.4.4.2 2002 Sediment Sampling

Sediment samples were collected from six locations (DTSD05, DTSD06, DTSD07, DTSD08, DTSD09, and DTSD10) in the unnamed creek downgradient of the BDDT. The samples were analyzed for VOCs, PAHs, PCBs, pesticides, herbicides, and TAL inorganics. The laboratory analytical results from this sampling event are summarized in Table 5-8 and the sample locations are depicted in Figure 5-2.

VOCs. Three VOCs (acetone, carbon disulfide and toluene) were detected in the sediment samples (see Table 5-8). The reported concentrations were several orders of magnitude below applicable industrial and residential RSLs. The detected constituents were also detected in the laboratory method blanks for these samples; therefore, it is likely that the detections are unrelated to the BDDT.

PAHs. A total of seventeen PAHs were detected in the sediment samples from the creek (see Table 5-8). Benzo(a)pyrene was detected at concentrations above the industrial RSL at sample locations DTSD05 and DTSD10. Benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were also detected at DTSD05 and DTSD10 at concentrations above residential RSLs. The detected PAH concentrations were less than residential screening levels in the other sediment samples.

PCBs. PCBs were not detected in any of the sediment samples (see Table 5-8).

Pesticides. Six pesticides (4,4'-DDD, 4,4"DDE, 4,4'DDT, alpha-chlordane, and delta-BHC) were detected in the sediment at sample locations DTSD05 and DTSD07 (see Table 5-8). The detected concentrations were all several orders of magnitude below their respective residential screening levels.

Herbicides. Herbicides were not detected in any of the sediment samples (see Table 5-8).

TAL Inorganics. Several inorganics were detected in the sediment samples (see Table 5-8); however, the detected concentrations were either below the applicable residential and industrial screening levels or the facility-wide background inorganics concentrations.

5.4.4.3 2002 Surface Water Sampling

Surface water samples (DTSW05, DTSW06, DTSW07, DTSW08, DTSW09, and DTSW10) were collected at each of the six 2002 sediment sample locations discussed in Section 5.4.4.2. The samples were analyzed for VOCs, PAHs, PCBs, pesticides, herbicides, perchlorate, TAL inorganics, and hardness. The laboratory analytical results from this sampling event are summarized in Table 5-9 and the sample locations are depicted in Figure 5-2.

VOCs. Two VOCs (carbon disulfide and chloroform) were detected in the surface water samples. However, the reported concentrations were below their respective tap water RSLs (See Table 5-9).

PAHs. Five PAH constituents (naphthalene, 2-methylnaphthalene, acenaphthene, acenaphthylene, and fluorine) were detected in surface water samples. The reported concentrations were below their respective tap water RSLs (See Table 5-9).

Herbicides. Herbicides were not detected in any of the surface water samples (see Table 5-9).

Pesticides. Three pesticides (4,4'-DDT, dieldrin, and endrin ketone) were detected at sample locations DTSW05 and DTSW07 (see Table 5-9). The detected concentrations of dieldrin were above the tap water RSLs at both sample locations. No other pesticides were detected in surface water.

PCBs. PCBs were not detected in any of the surface water samples (see Table 5-9).

Perchlorate. Perchlorate was not detected in any of the surface water samples (see Table 5-9).

Building Debris Disposal Trench

TAL Inorganics. Several inorganic constituents were detected in the surface water samples (see Table 5-9); however, the detected concentrations were all below applicable tap water RSLs.

Hardness. Hardness of the surface water samples ranged from 181 milligrams per liter (mg/L) to 204 mg/L (see Table 5-9). Hardness is an indicator parameter and does not have an associated RSL.

5.4.5 Additional Characterization, Shaw, 2004

Shaw completed additional soil sampling activities at the BDDT site in 2004 that were designed to assess the horizontal and vertical extent of elevated PAHs in the open area at the downgradient end of the BDDT (Shaw 2007). This investigation included:

- 42 Surface soil samples (DTSB48 through DTSB89) were collected from parallel sample lines downslope from the BDDT to complete the horizontal delineation. These samples were collected from 0-0.5 ft bgs.

- 5 Subsurface soil samples (DTSB48, DTSB55, DTSB59, DTSB67, and DTSB77) were collected to complete the vertical delineation of PAH detections. These samples were collected from 1-3 ft bgs.

All of the soil samples collected during this event were submitted for laboratory analysis of low-level PAHs. Thirty-three of the samples were also submitted for laboratory analysis of PCBs. The laboratory analytical results from this sampling event are summarized in Table 5-10, and the sampling locations are depicted in Figure 5-2.

PAHs. Similar to the 2002 Investigation, a total of seventeen different PAHs were detected in surface soil samples in the open area at the downgradient end of the BDDT (see Table 5-10). Of the detected PAHs only seven constituents [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene] were detected at concentrations above applicable industrial and/or residential RSLs. Only 14 of the 42 sample locations contained PAHs at concentrations above industrial RSLs; while a total of 25 sample locations contained PAHs at concentrations above residential RSLs. Only two of the five subsurface soil sample locations (DTSW48 and DTSB55) contained PAHs above applicable industrial and/or residential RSLs.

PCBs. PCBs were not detected in any of the soil samples (See Table 5-10).

5.4.6 Remedial Investigation, ARCADIS, 2008

In accordance with Remedial Investigation Work Plan Addendum 27 (ARCADIS 2008b), ARCADIS completed additional RI activities at the BDDT in 2008 to finalize the characterization and delineation work at this site. This investigation included the following components:

- Two soil borings were completed in the area immediately downgradient of the disposal trench to complete the vertical delineation of PAH detections. Soil samples were collected from 0-0.5 ft bgs, 2-3 ft bgs, and 3-4 ft bgs at each location. The surface soil (0-0.5 ft bgs) samples were labeled BDDT-SS01 and BDDT-SS02. The subsurface soil samples were labeled BDDT-SB01 and BDDT-SS02.

- Six soil samples (BDDT-SS03 through BDDT-SS08) were collected from the perimeter of the open area between the two hills at the downslope end of the BDDT to confirm that the horizontal extent of PAH detections above screening levels had been fully delineated

- Four co-located surface water (BDDT-SW01 through BDDT-SW04) and sediment samples (BDDT-SE01 through BDDT-SE04) were collected from the unnamed creek downgradient of the BDDT to evaluate the potential for on-going effects to the creek.

All of the soil, sediment, and surface water samples were analyzed for low-level PAHs by USEPA Method 8270. The analytical results are summarized in Tables 5-11, 5-12, and 5-13, respectively. The sample locations are depicted in Figure 5-2. The laboratory analytical reports from ARCADIS' 2008 sampling event are included in Appendix C.

5.4.6.1 2008 Soil Sampling Results

The analytical results from the two surface soil samples (BDDT-SS001 and BDDT-SS002) and two subsurface soil borings (BDDT-SB001 and BDDT-SB002) completed immediately downgradient from the former disposal area indicated the following:

- A total of 16 different PAH constituents were detected in surface and subsurface soil samples (See Table 5-11).

Building Debris Disposal Trench

- Benzo(a)pyrene was detected at concentrations above its industrial RSL in the two surface soil samples (BDDT-SS01 and BDDT-SS02). Benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were also detected at concentrations higher than their residential RSLs at these locations. No other PAHs were detected at concentrations above applicable RSLs.

- Benzo(a)pyrene was detected at concentrations above the residential RSL in the samples collected at 2-3 ft bgs at both BDDT-SB001 and BDDT-SB002. The sample from 3-4 ft bgs at BDDT-SB002 also contained benzo(a)pyrene at concentrations above the residential RSL.

- Bedrock was encountered at approximately 5 ft bgs at both BDDT-SB001 and BDDT-SB002.

The analytical results from the soil samples collected at the perimeter of the open area downgradient of the disposal trench (BDDT-SS03 through BDDT-SS08) indicated the following:

- A total of 8 different PAHs were detected in various soil samples (See Table 5-11). However, the detected concentrations were all below applicable residential RSLs. This confirms that the horizontal and vertical delineation of PAHs in soil at the BDDT has been completed.

5.4.6.2   2008 Sediment and Surface Water Results

The laboratory analytical results from the four sediment samples collected from the unnamed creek downgradient of the BDDT indicated the following:

- No PAHs were detected in the two sediment samples collected closest to the BDDT (BDDT-SE001 and BDDT-SE002).
- Several PAHs were detected in the two sediment samples collected downstream from the BDDT (BDDT-SE003 and BDDT-SE004) (see Table 5-12). None of the detected PAHs were at concentrations above industrial RSL; however, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene were detected at concentrations above their residential RSLs at sediment sample location BDDT-SE04.

Building Debris Disposal Trench

The laboratory analytical results from the four surface water samples collected during the 2008 sampling event indicated the following:

- No PAHs were detected in any of the surface water samples (see Table 5-13).

5.5 Nature and Extent of Constituent Detections

The analytical results presented in the previous sections indicate that soil at the BDDT site was affected by historical disposal activities that included the placement of building debris/materials in a surface water drainage pathway. Soil samples collected from the disposal area confirmed that PAHs were present in soil underneath the debris at concentrations above applicable industrial screening levels. Site restoration activities were completed in 1998 that included the removal of the building debris and stained soils, replacement of the excavated soil with clean fill, and lining the trench with geotextile fabric and rip rap to prevent erosion. It should be noted that sampling performed in 1998 prior to the placement of the clean fill, geotextile liner, and rip rap indicated that PAHs were left in place at concentrations above residential and industrial RSLs. A site map depicting the PAH detections in the disposal trench from the 1998 site investigations is presented as Figure 5-3. The site restoration activities mitigated the source area and potential exposure pathways along the trench; therefore, subsequent investigations focused on soil, sediments, and surface water, downgradient of the trench. This section summarizes the nature and extent of the constituent detections observed during the course of environmental investigation at the site.

5.5.1 Soil

A total of 55 surface soil samples and 11 subsurface soil samples have been collected from the open area between the trench and the downgradient creek to characterize and delineate the extent of constituents in soil resulting from the former disposal activities at the BDDT. Due to the physical characteristics of the site (i.e., topography and grass groundcover), this area is a natural depositional area for media (i.e., soil and debris) that may have washed out of the trench prior to the site restoration activities. The sampling results indicate that several PAHs are present in surface soils downgradient of the trench. However, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene are the only PAHs that have been detected at concentrations above residential and industrial RSLs (see SVOC and PAH analytical results presented in historical sampling tables). The horizontal extent of the PAHs at concentrations

Building Debris Disposal Trench

above industrial and residential RSLs has been fully delineated as confirmed by the samples collected in 2004 and 2008, and are contained within area of approximately 0.4-acres. A site map depicting PAH detections in soil downgradient of the restored trench is presented as Figure 5-4.

The subsurface soil samples confirmed that the PAHs are confined to surface soil (0-1 ft bgs) throughout most of the open area between the former disposal area and the downgradient creek. However, two soil borings completed immediately downgradient of the former disposal area indicated that PAHs were present at concentrations above residential RSLs at depths up to 4 ft bgs. Bedrock is present at approximately 5 ft bgs throughout the BDDT area so the elevated PAH concentrations are not expected to go any deeper. Based the findings of attempted monitoring well installation activities at the BDDT in 2008, groundwater is not present in the bedrock formations at the BDDT to at least a depth of 75 ft (see Section 2.2.6).

Although two pesticides and four herbicides were detected in one surface soil sample collected immediately downgradient of the disposal trench (DTSB46), the herbicide MCPP was the only constituent detected in this sample at a concentration above a residential RSL.

Inorganics were detected in both surface and subsurface soil samples from the BDDT area. While the detected concentrations of several of these inorganics were higher than applicable residential and or industrial RSLs, the detected concentrations were typically below the background concentrations presented in the facility-wide background study. The only exceptions were cobalt, iron, and manganese. These constituents were each detected in one sample at concentrations above background and applicable RSLs. Cobalt and manganese were detected at concentrations above the industrial RSL and established background levels at 1998 sample location DTSS2 and iron was detected at a concentration above the residential RSL and established background levels at 1998 sample location DTSS3. Both the DTSS2 and DTSS3 sample locations were in the open area downgradient of the trench. Cobalt, iron, and manganese were not detected at elevated concentrations in the former disposal trench; therefore, it is likely that these isolated detections were either laboratory anomalies or the metals are naturally occurring at higher concentrations in this area.

Explosives and PCBs have not been detected in any of the soil samples collected at the BDDT.

Building Debris Disposal Trench

A figure depicting non-PAH constituent detections at the BDDT is presented in Figure 5-5.

5.5.2 Sediment

Sediment sampling events were conducted in 1998, 2002, and 2008 within the unnamed creek downgradient of the BDDT to evaluate whether creek sediments have been affected by ongoing releases from the site. A total of seventeen sediment samples have been collected during these investigations. A site map depicting the constituents detected in sediment samples at the site is presented in Figure 5-6.

A total of 17 different PAH constituents have been detected in sediment samples from the unnamed creek. The majority of the detections occurred during the June 2002 sampling event, which was conducted approximately 4 years following the completion of the site restoration activities. During the 2002 event, PAHs were detected at varying concentrations in six separate sediment samples; including two samples collected upgradient of the BDDT (DTSD08 and DTSD09). However, only two samples during the 2002 investigation (DTSD5 and DTSD10 – both of which are located downstream of the BDDT) contained benzo(a)pyrene at concentrations above industrial RSLs. No other PAHs were detected at concentrations above industrial RSLs. Although, DTSD5 and DTSD10 did contain benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene at concentrations higher than residential RSLs.

During the 2008 sampling event no PAHs were detected at concentrations above industrial RSLs. Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene were detected at concentrations above the residential RSL in the sample collected furthest downstream from the BDDT (BDDT-SE004). The two samples collected closest to the BDDT (BDDT-SE001 and BDDT-SE002) did not have any PAH detections. These results appear to indicate the PAH concentrations in the stream sediments may be attenuating over time or are currently a result of runoff from the perimeter road affecting the results at the most downgradient sample.

The stream sediment samples have been found to contain several inorganics at concentrations similar to those observed in soil samples from the BDDT and those reported in the Facility-Wide Background Study. The only inorganics that have been detected at concentrations above established background soil levels and applicable RSLs are iron and manganese; these detections both occurred in one sample in 1998 (DTSD04). As neither of these constituents were detected above applicable screening criteria in soil from the BDDT, the detections in sediment are believed to be naturally occurring.

No explosives, herbicides, or PCBs were detected during the course of sediment sampling.

5.5.3 Surface Water

A total of 17 surface water samples have been collected from the unnamed stream downgradient of the BDDT during the course of environmental investigation at this site. The surface water samples were collected in conjunction with (i.e., co-located with) the sediment samples to aid in determining if surface water quality was being influenced by the sediments, or vice versa. A site map depicting constituents detected in surface water samples is presented in Figure 5-7.

Despite the PAH detections in surface soil and sediment at the BDDT, PAHs/SVOCs have rarely been detected in surface water in the unnamed creek. During the 2002 sampling event 2-methylnapthalene, naphthalene, acenaphthene, acenaphthylene, and fluorene were detected at low concentrations within several samples. The detected concentrations were several orders of magnitude below applicable tap water RSLs, and laboratory data validation indicated that many of these constituents were also detected in a laboratory blank samples. No PAHs were detected in surface water samples collected in 2008 which indicates that the PAHs detected in site soils and sediments are not having any adverse effects to surface water.

The pesticide dieldrin was detected in two samples during the 2002 investigation (DTSW05 and DTSW07) at concentrations above the tap water RSL. Dieldrin was also detected in the sediment samples at these locations; albeit at concentrations below applicable residential RSL. Dieldrin was not detected in soil at the BDDT, therefore, it is likely that the detection in surface water is not site related. It should also be noted that during the 2002 sampling event, dieldrin was detected at a concentration above the tap water RSL in several samples collected from the unnamed stream far upstream of the BDDT; including one sample that was collected before the stream flows onto the RFAAP-NRU facility (WBGSW14 – see Table 9-12). This further indicates that the dieldrin detection is likely due to an off-site source.

Several inorganics have been detected in all surface water samples collected both upstream and downstream of the unnamed creek's confluence with the BDDT. With the exception of thallium, which was detected in three samples during 1998

Building Debris Disposal Trench

[DTSW2(7/17/98), DTSW2(8/17/98), and DTSW4(8/17/98], the detected inorganics concentrations have been below applicable tap water RSLs. Thallium was not detected in any of the six surface water samples collected during the 2002 sampling event and thallium has not been detected at concentrations above established background concentrations in soil or sediment at the site. Therefore, the 1998 detections do not appear to be site related.

No PCBs, herbicides, explosives, or perchlorate were detected during the course of surface water sampling.

5.6 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. Risk assessment datasets for soil, sediment, and surface water for the BDDT were prepared then summarized and statistically analyzed. Risk assessment datasets summaries highlighting: the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPC are presented in Tables 5-14 through 5-18.

Previous site restoration activities mitigated the source area and potential exposure pathways along the portion of the trench that is now covered by a geotextile liner and riprap. Although the soils in the riprap covered portion of the BDDT are not currently accessible for either human or wildlife exposures, the data from these locations were included in the soil dataset to evaluate potential risks if the rip rap was to be removed in the future so that the soils under it would become accessible. Because the source of COPCs in the rip rap covered portion of the site differed from the source in the remainder of the BDDT, an additional analysis was also conducted to determine if potential risks would differ if the soils in that portion of the BDDT were to become accessible in the future and future activities were focused on that area.

5.7 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with constituents detected in soil, sediment and surface water samples collected at the BDDT. The risk assessment approach follows the Radford Army Ammunition Plant Final Master Work Plan (URS 2003).

Building Debris Disposal Trench

5.7.1 Selection of Constituents of Potential Concern

This section discusses the selection of COPCs for the HHRA for each medium at the BDDT.

5.7.1.1 Surface Soil

Surface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 5-19 presents the selection of surface soil COPCs for the human health risk assessment. The COPCs for surface soil are:

- **SVOCs/PAHs:** carbazole, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, and naphthalene.
- **Herbicides:** MCPP
- **Inorganics:** cobalt, iron, and manganese

5.7.1.2 Combined Surface and Subsurface Soil

Combined surface and subsurface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 5-20 presents the selection of the combined surface and subsurface soil COPCs for the human health risk assessment. As summarized in Table 5-20, 13 constituents were identified as COPCs in combined surface and subsurface soil. These constituents include:

- **SVOCs/PAHs:** carbazole, dibenzofuran, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, and naphthalene.
- **Herbicides:** MCPP
- **Inorganics:** cobalt, iron, and manganese

5.7.1.3 Sediment

Sediment COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 5-21 presents the selection of sediment COPCs for the human health risk assessment. As summarized in Table 5-21, the following 12 constituents were identified as COPCs in sediment:

- **SVOCs/PAHs:** benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, dibenzo[a,h]anthracene, and indeno[1,2,3-cd]pyrene.

- **Inorganics**: aluminum, arsenic, cobalt, iron, manganese, thallium, and vanadium.

5.7.1.4 Surface Water

Surface water COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for tap water. Table 5-22 presents the selection of surface water COPCs for the human health risk assessment. As summarized in Table 5-22, four constituents were identified as COPCs in surface water:

- **VOCs:** bromodichloromethane and chloroform

- **Pesticides:** dieldrin

- **Inorganics:** thallium

5.7.2 Human Health Risk Characterization

Methods used to calculate the excess lifetime cancer risks and non-cancer hazards are described in Appendix A. Tables presented in the constituent and pathway-specific risk calculations for each of the receptors at the BDDT are presented in Appendix A. The results of the risk calculations are summarized below. The excess lifetime cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the BDDT are presented in Appendix A and are summarized in the tables and subsections below.

Building Debris Disposal Trench

5.7.2.1 Site Worker

A current or future site worker could be present at the BDDT area, and could be exposed to surface soil, sediment, surface water, or combined surface and subsurface soil via vapor migration to indoor air. The ELCR and non-cancer hazard index for site worker exposure to each medium at the entire BDDT are presented in Appendix A (Tables A-HHRA-6 through A-HHRA-9), and are summarized in Table 5-24. The ELCR and non-cancer hazard index for site worker exposure to each medium at the rip rap portion only are presented in Appendix A (Tables A-HHRA-20 through A-HHRA-21), and are summarized in Table 5-24a. The following ELCRs and non-cancer hazard indices have been calculated:

Summary of Calculated ELCRs for the Site Worker Exposure Scenarios for Entire BDDT and Rip Rap Portion Only

Site Worker	ELCR at BDDT	ELCR for Rip Rap Portion
Surface Soil - Direct Contact	5E-05	2E-05
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	NA	NA
Sediment – Wading	1E-05	NA
Surface Water – Wading	4E-07	NA
TOTAL SITE RISKS (Site Worker):	**7E-05**	**2E-05**

*See Appendix A for individual tables.

Summary of Calculated HIs for the Site Worker Exposure Scenarios for Entire BDDT and Rip Rap Portion Only

Site Worker	HI at BDDT	HI for Rip Rap Portion
Surface Soil - Direct Contact	0.5	0.1
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	0.04	0.1
Sediment – Wading	0.02	NA
Surface Water – Wading	0.04	NA
TOTAL SITE RISKS (Site Worker):	**0.6**	**0.3**

*See Appendix A for individual tables.

The total cumulative ELCR for site workers exposed to surface soil, sediment, surface water, and air at the entire BDDT is 7×10^{-5} and 2×10^{-5} for the rip rap portion only both of which are within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.6 for the entire BDDT and 0.3 for the rip rap portion only, both of which are less than the benchmark of 1.

Building Debris Disposal Trench

5.7.2.2 Hypothetical Future Construction Worker

A hypothetical future construction worker could be present at the BDDT area, and could be exposed to combined surface and subsurface soil. The ELCR and non-cancer hazard index for hypothetical future construction worker exposure to soil are summarized below.

Summary of Calculated ELCRs for the Construction Worker Exposure Scenario for Entire BDDT and Rip Rap Portion Only

Construction Worker	ELCR at BDDT	ELCR for Rip Rap Portion
Combined Surface and Subsurface Soil – Direct Contact	2E-06	2E-06
TOTAL SITE RISKS (Construction Worker):	**2E-06**	**2E-06**

*See Appendix A for individual tables.

Summary of Calculated HIs for the Construction Worker Exposure Scenario for Entire BDDT and Rip Rap Portion Only

Construction Worker	HI at BDDT	HI for Rip Rap Portion
Combined Surface and Subsurface Soil – Direct Contact	1	0.4
TOTAL SITE RISKS (Construction Worker):	**1**	**0.4**

*See Appendix A for individual tables.

The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the entire BDDT or for the rip rap portion only was 2×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 1 for the entire BDDT which is equivalent to the benchmark of 1. When the HI is segregated into target site and critical effects, all hazards are less than the benchmark. For the rip rap portion only, the HI for hypothetical future construction workers is 0.4, which is less than the benchmark.

5.7.2.3 Hypothetical Future Residents

A hypothetical future adult or child resident could be present at the BDDT area, and could be exposed to combined surface and subsurface soil, sediment, surface water or combined surface and subsurface soil via vapor migration to indoor air. The ELCR and non-cancer hazard index for hypothetical future adult or child resident exposure to each medium are summarized below.

Building Debris Disposal Trench

Summary of Calculated ELCRs for Hypothetical Future Residential Exposures for Entire BDDT and Rip Rap Portion Only.

Hypothetical Future Resident	ELCR at BDDT	ELCR for Rip Rap Portion
Combined Surface and Subsurface Soil - Direct Contact	4E-04	3E-04
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	NA	NA
Sediment – Wading	5E-05	NA
Surface Water – Wading	2E-07	NA
TOTAL SITE RISKS (Resident):	**4E-04**	**3E-04**

*See Appendix A for individual tables.

Summary of Calculated HIs for Hypothetical Future Residential Exposures for Entire BDDT and Rip Rap Portion Only.

Hypothetical Future Adult Resident	HI at BDDT	HI for Rip Rap Portion
Combined Surface and Subsurface Soil - Direct Contact	0.5	0.2
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	0.06	0.2
Sediment – Wading	0.04	NA
Surface Water – Wading	0.01	NA
TOTAL SITE RISKS (Adult Resident):	0.6	0.4
Hypothetical Future Child Resident		
Combined Surface and Subsurface Soil - Direct Contact	4	2
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	0.06	0.2
Sediment – Wading	0.3	NA
Surface Water - Wading	0.04	NA
TOTAL SITE RISKS (Child Resident):	**5**	**2**

*See Appendix A for individual tables.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, surface water, and air for the entire BDDT is 4×10^{-4}, which is above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. For the rip rap portion only, the ELCR for hypothetical future residents was 3×10^{-4}, which is also above the target risk range. The total cumulative HI for hypothetical future adult residents is 0.6 for the entire BDDT and 0.4 for the rip rap portion only, which are both less than the benchmark of 1.

The total cumulative HI for hypothetical future child residents is 5 for the entire BDDT and 2 for the rip rap portion only, both of which are greater than the benchmark of 1. When the HI for the entire BDDT is segregated into target site and critical effects, hazards were only greater than the benchmark of 1 in the skin due to the presence of cobalt. In the rip rap area, hazards segregated by target organ are all less than 1.

Building Debris Disposal Trench

5.7.3 Human Health Risk Summary

Tables 5-24 and 5-24a summarize the calculated cancer risks and non-cancer hazards for the site worker, construction worker, and residential exposure scenarios for the entire BDDT site and the rip rap covered portion only, respectively. As shown in the table above, the total ELCR values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for the site worker and construction worker scenarios are below or within the generally acceptable range of 10^{-6} to 10^{-4} for cancer risk. However, the total ELCRs for the future hypothetical resident exposed to surface and subsurface soil at the BDDT site as a whole, and within the rip rap covered portions of the site only, were both above the acceptable range of 10^{-6} to 10^{-4} for cancer risk. The driver for the elevated ELCRs in both cases was benzo(a)pyrene.

The total HI values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below or equal to the benchmark of 1 for non-cancer hazard, with the exception of hypothetical future child residential exposures to combined surface and subsurface soil. When the HIs are segregated into target site and critical effects, hazards were only greater than the benchmark of 1 in the skin for hypothetical future child resident exposure to the entire BDDT only. Cobalt is the constituent exceeding the benchmark in all of these exposure scenarios. The cobalt risks are being driven by a single sample from the area downgradient of the trench that had a concentration above established background levels. All other cobalt detections at the site were within background levels.

The results of the risk assessment for the BDDT indicate that industrial redevelopment of the entire area would not result in risks or hazards outside the regulatory benchmarks. However, the presence of benzo(a)pyrene in surface soil at the site, and within the rip rap covered portion of the site only, resulted in slightly elevated cancer risks under residential land use scenarios. Therefore, the site is not suitable for residential development in its current state. The maximum detected concentration of cobalt at the site also resulted in slightly elevated non-cancer hazards for child residents. All of the other detections of cobalt at the BDDT were within the background range and there is no evidence that suggests cobalt was utilized or disposed of at the BDDT. Therefore, the one elevated cobalt detection is likely the result of an isolated natural anomaly.

Building Debris Disposal Trench

5.8 Ecological Risk Assessment

The purpose of the ERA is to evaluate whether ecological receptors may be adversely impacted by exposure to site-related constituents detected in surface soil, sediment, and surface water at the BDDT. The ERA approach is based on the Master Work Plan (URS 2003) in compliance with CERCLA/SARA. The ERA was conducted in a manner consistent with Virginia policy and USEPA guidance for ecological risk assessment (USEPA 2001a; 2000b; 1997c). This ERA is intended to provide input for risk management decision-making for the BDDT, while maintaining a conservative approach protective of wildlife populations and communities. In accordance with USEPA guidance, the ERA for the BDDT commenced with a SLERA and then concluded with a BERA (USEPA 1997c).

This section summarizes the occurrence of constituents in each medium and identifies COPECs at the BDDT for the ERA; identifies the potential ecological exposure scenarios relevant to the BDDT; and presents the estimated ecological risks associated with the identified COPECs and the relevant ecological exposure scenarios at the BDDT. Methodologies for data summary and selection of COPECs, exposure assessment, and toxicity assessment for the ERA were presented in Section 2.4.

5.8.1 Selection of Constituents of Potential Ecological Concern

This section discusses the selection of COPECs for each medium. HQs greater than 1 indicate that further evaluation may be warranted. Therefore, the constituents with HQs greater than 1 are carried forward as COPECs into the BERA.

5.8.1.1 Surface Soil

Surface soil COPECs were selected by comparing the analytical data with ecological screening levels (ESLs) from the following sources in order of priority: USEPA (2005b) EcoSSLs, USEPA (2003e) Region 5 Ecological Screening Levels, and ORNL values for soil (Efroymson et al. 1997a,b). Table 5-25 presents the selection of surface soil COPECs for the ecological risk assessment. As summarized in Table 5-25, a total of 30 constituents were identified as COPECs in surface soil as follows:

- **SVOCs:** carbazole and dibenzofuran

- **PAHs:** 2-methylnaphthalene, acenaphthylene, acenaphthene, anthracene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(g,h,i)perylene

Building Debris Disposal Trench

benzo(k)fluoranthene, dibenzo(a,h)anthracene, fluorene, indeno(1,2,3-cd)pyrene, benzo(a)pyrene, chrysene, naphthalene, fluoranthene, phenanthrene, and pyrene**Inorganics*:*** cobalt, copper, iron, manganese, selenium, and lead

- **Herbicides:** dalapon, dicamba, and MCPP

- **Pesticides:** 2,4-D and methoxychlor

5.8.1.2 Sediment

Sediment COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Sediment Screening Levels; ORNL values (Jones et al. 1997); and USEPA (2003a) Region 5 Ecological Screening Levels for sediment. Table 5-26 presents the selection of sediment COPECs for the ecological risk assessment. As summarized in Table 5-26, a total of 37 constituents were identified as COPECs in sediment as follows:

- **VOCs:** acetone and carbon disulfide.

- **PAHs:** 2-methylnaphthalene; acenaphthylene, acenaphthene; anthracene; benzo(a)anthracene; benzo(a)pyrene; benzo(b)fluoranthene; benzo(g,h,i)perylene; benzo(k)fluoranthene; chrysene; dibenzo(a,h)anthracene; fluoranthene; fluorene; indeno(1,2,3-cd)pyrene; phenanthrene; and pyrene.

- **Inorganics:** arsenic, barium, beryllium, chromium, copper, iron, lead, manganese, nickel, thallium, vanadium, and zinc.

5.8.1.3 Surface Water

Surface water COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Surface Water Screening Levels; ORNL values (Suter and Tsao 1996); USEPA (2003a) Region 5 Ecological Screening Levels; and USEPA (2008e) Ambient Water Quality Criteria for surface water. Table 5-27 presents the selection of surface water COPECs for the ecological risk assessment. Surface water COPECs are:

- **VOCs:** Chloroform and bromodichloromethane

- **Pesticides:** 4,4'-DDT, dieldrin

PAHs: acenaphthene, acenaphthylene, fluorene

- **Inorganics:** aluminum, barium, copper, iron; lead, nickel, silver, thallium, and zinc

5.8.2 Summary of Selected Constituents of Potential Ecological Concern

A total of 30 constituents were selected as COPECs in surface soil, 37constituents were selected as COPECs in sediment, and 16 constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was bioaccumulative or an HQ could not be calculated because an ESL was not available.

5.8.3 Refinement of Risk Calculations for Direct Contact Constituents of Potential Ecological Concern

The list of COPECs identified in the BERA was reevaluated by calculating refined HQs. The refined HQs were calculated for the COPECs identified in the SLERA using refined EPCs. Constituents identified as COPECs in the BERA that were bioaccumulative were carried forward into food chain models. The results of the recalculation of the HQs for the BDDT are summarized in the subsections below.

5.8.3.1 Surface Soil

Thirty COPECs in surface soil were carried forward into the BERA. When refined EPCs were compared with the ESLs, only eight constituents [benzo(a)anthracene; benzo(a)pyrene; chrysene; naphthalene; cobalt; copper; manganese, and lead] had a refined HQ greater than 1. In addition, ESLs were not available for six other constituents (carbazole; dibenzofuran; dalapon; dicamba; MCPP; and iron). The BERA results for surface soil COPECs at the BDDT are presented in Table 5-28.

Of the thirty COPECs evaluated, twenty were considered bioaccumulative and were evaluated in the terrestrial food chain model presented in Section 5.8.4.1.

5.8.3.2 Sediment

A total of thirty-seven COPECs in sediment were carried forward into the BERA. When refined EPCs were compared with the ESLs, a total of 15 constituents [acetone; carbon disulfide; 2-methylnaphthlene; acenaphthene; anthracene; benzo(a)anthracene; benzo(a)pyrene; chrysene; dibenzo(a,h)anthracene; fluoranthene; indeno(1,2,3-cd)pyrene; phenanthrene; pyrene; iron; and manganese] had a refined HQ greater than 1. In addition, ESLs were not available for four other constituents (barium, beryllium, thallium, and vanadium). The BERA results for sediment COPECs at the BDDT are presented in Table 5-29.

Of the COPECs evaluated, twenty-seven were identified as bioaccumulative and evaluated in the aquatic food chain model presented in Section 5.8.4.2.

5.8.3.3 Surface Water

Sixteen COPECs in surface water were carried forward into the BERA. When refined EPCs were compared with the ESLs, only five constituents (4,4'-DDT; aluminum; barium; copper; and thallium) had a refined HQ greater than 1. In addition, an ESL was not available for bromodichloromethane. The BERA results for surface water COPECs at the BDDT are presented in Table 5-30.

Of the COPECs evaluated, eight were also identified as bioaccumulative and were evaluated in the aquatic food chain model (Section 5.8.4.2).

5.8.4 Refinement of Assessment and Measurement Endpoints for Bioaccumulative COPECs

Food chain modeling was conducted at the BDDT in order to evaluate the potential ecological effects of the bioaccumulative COPECs in soil, sediment, and surface water on the receptors identified in Appendix A. COPECs identified in soil were evaluated in the terrestrial food chain, and COPECs identified in sediment and surface water were evaluated in the aquatic food chain. The results for both the maximum and refined scenarios of these models are presented in Appendix A.

5.8.4.1 Terrestrial Food chain Model

As summarized in Table 5-31, the refined scenario LOAEL and NOAEL HQs for both the short-tailed shrew and the American robin were less than or equal to 1 for most COPECs. A few PAHs have NOAEL HQs above 1, however, with the exception of dibenzo(a,h)anthracene none has a LOAEL HQ above 1 or a NOAEL HQ above 10. The TRV for dibenzo(a,h)anthracene was conservatively extrapolated from acute toxicity values so the risks presented are likely to overestimate the actual risks. These results indicate that individual shrews and robins (or other insectivorous mammals and birds) exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of terrestrial food chain modeling HQs, adverse effects are not expected for wildlife exposed to bioaccumulative COPECs in soil at the BDDT.

5.8.4.2 Aquatic Food chain Model

As summarized in Table 5-32, the refined scenario LOAEL and NOAEL HQs for both the mink and the great blue heron were less than or equal to 1 for all COPECs identified in sediment and/or surface water with the exception of arsenic which had a slight exceedance of the NOAEL HQ for mink.. These results indicate that mink and herons (or other piscivorous mammals and birds) exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of aquatic food chain modeling HQs, adverse effects are not expected for wildlife exposed to bioaccumulative COPECs in sediment and/or surface water at the BDDT.

5.8.5 Ecological Risk Summary

Screening-level and baseline risk assessments were completed for the BDDT. After the SLERA, 30 constituents were selected as COPECs in surface soil, 37constituents were selected as COPECs in sediment, and 16 constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was considered bioaccumulative, or an HQ could not be calculated because an ESL was not available. After the BERA, 14 constituents in surface soil, 19 constituents in sediment, and six constituents in surface water were retained because the HQs were greater than 1 or an HQ could not be calculated because an ESL was not available. In addition, food chain modeling was evaluated for all those constituents identified as bioaccumulative.

Tables 5-31 and 5-32 summarize the constituents in surface soil, sediment, and surface water carried through the BERA and evaluated in the terrestrial and/or aquatic food chain models. As shown in these tables, the majority of constituents evaluated in the terrestrial and aquatic food chain refined scenarios had LOAEL and NOAEL HQs

Building Debris Disposal Trench

less than or equal to 1. Those that exceeded 1 were below 10 with the exception of the NOAEL HQ associated with dibenzo(a,h)anthracene exposures to shrew. However, as noted previously, that chemical was detected in less than half of the samples analyzed, and the TRVs evaluated were conservatively extrapolated from acute studies, so the risks are likely overestimated. Based on the overall analysis of the ERA for the BDDT, the results indicate that adverse effects are not expected for wildlife at the site.

As discussed in Section 5.1, previous site restoration activities mitigated the source area and potential exposure pathways along the trench. Because the soils in the riprap covered portion of the BDDT were not included in the soil dataset for the ERA, the potential impact of this approach was evaluated by calculating the risks associated with the rip-rap soils, as detailed in Appendix A. Based on the results of that assessment, risks associated with the rip-rap soils are less than or very similar to those associated with the rest of BDDT.

5.9 BDDT Summary and Conclusions

The BDDT was formerly an ephemeral unlined natural drainage swale that channeled surface water runoff from the surrounding area towards the unnamed creek which passes through the southwestern portion of the RFAAP-NRU. An approximately 600-ft long section of the drainage swale was utilized for the disposal of miscellaneous building debris derived from the dismantling of various structures at the RFAAP-NRU. The building debris consisted of concrete, wood, and rusted and broken drums of a black, tarry substance believed to be roofing tar. Samples collected from the trench indicated that PAHs were present in soils underlying the debris at concentrations above applicable screening levels. Site restoration activities were performed at the BDDT in 1998 as part of a remedial investigation that included the removal of all building debris and any visibly stained soil from the trench. The excavated material was replaced with clean fill and the trench was lined with a geotextile fabric and filled with riprap to minimize the potential for erosion. The site restoration activities mitigated the source area and potential exposure pathways along the trench; therefore, subsequent investigations focused on soil, sediments, and surface water, downgradient of the trench.

Sampling activities performed at the BDDT between 1998 and 2008 focused on the areas downslope of the trench that may have been affected by the transport of constituents prior to the site restoration activities. These areas included an open area between two hills at the downgradient reach of the trench and an unnamed stream located further downslope. Based on the physical characteristics of the site, the

Building Debris Disposal Trench

stream and the open area downgradient of the disposal area would have been natural depositional areas for media (i.e., soil and debris particles) that may have washed out of the trench prior to the site restoration activities. The open area downgradient of the trench is heavily vegetated with tall grasses and has a gentle slope towards the downgradient stream. Bedrock is present at approximately 5 ft bgs throughout the BDDT Analyte classes included during the various phases of investigation at the BDDT have included VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides, explosives, and inorganics.

A total of 55 surface soil samples and 11 subsurface soil samples were collected from the open area between the trench and the downgradient creek to characterize and delineate the extent of constituents in soil resulting from the former disposal activities at the BDDT. The sampling results indicated that several PAHs were present in surface soils (i.e., 0 to 1 ft bgs). The detected concentrations of benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were present at concentrations above initial screening levels. Other constituents detected at concentrations above initial screening levels included the herbicide MCPP; and the metals cobalt, iron, and manganese. Cobalt, iron, manganese, and MCPP were each only detected in one surface soil sample at concentrations above the applicable screening criteria. No other constituents were detected at concentrations above the initial screening levels.

Soils: The delineation of the PAHs was completed during the 2008 sampling event which defined the outer edges of the PAH detections in surface soil. PAHs were detected at concentrations above initial screening levels in 34 of the 55 surface soil samples and in 6 subsurface soil samples. The 2008 sampling event also confirmed that the subsurface PAH detections are confined to a small area immediately downgradient of the end of the formal disposal area and only extend to a depth of approximately 4 ft bgs. PAH detections are not expected to extend any deeper due to the presence of shallow bedrock throughout the BDDT area.

Sediments: A total of 17 sediment and surface water samples were collected from the unnamed stream downslope of the BDDT area during environmental investigations conducted in 1998, 2002, and 2008. The sediment samples indicated that the PAHs benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cdpyrene) were present at concentrations above applicable screening criteria in two samples collected downstream of the BDDT in 2002. PAH concentrations

Building Debris Disposal Trench

decreased in the samples collected during 2008, with only the furthest downstream sample (BDDT-SD4) containing PAHs at concentrations above applicable screening levels. These results appear to indicate that the residual PAHs present in the surface soils within the open area downslope of the BDDT are not resulting in continued releases of PAHs to the stream. The only other constituents detected in sediment at concentrations above applicable screening levels were iron and manganese, which were only detected at concentrations above screening criteria in one sample DTSD3 in 1998.

Surface Water: The surface water data from the un-named stream have indicated that no PAHs have been detected at concentrations above tap water RSLs. The pesticide dieldrin was detected at a concentration above the tap water RSL in two samples collected in 2002. The VOCs bromodichloromethane and chloroform were detected above the tap water RSL in one sample in 1998. The inorganic constituent thallium was also detected above the tap water RSL in two samples collected in 1998 (thallium was not detected in any samples collected in 2002). The isolated occurrences of these detections, and the fact that dieldrin, bromodichloromethane, chloroform, and thallium were not identified as COPCs for the BDDT soils indicate that the BDDT area is not resulting in continued releases of these constituents. It should also be noted that during the 2002 sampling event, dieldrin was detected at a concentration above the tap water RSL in several samples collected from the unnamed stream, far upstream of the BDDT; including one sample that was collected before the stream flows onto the RFAAP-NRU facility (WBGSW14 – see Table 9-12). This indicates that the dieldrin detection is likely due to an off-site source.

An HHRA was conducted to evaluate exposure to COCPs in surface soil, combined surface and subsurface soil, sediment, and surface water for site workers, construction workers, hypothetical residents under both current and future land-use conditions. The HHRA considered data collected from the entire BDDT site as well as a second scenario that only included data collected from the rip rap covered portion of the site. The calculated excess lifetime cancer risks and hazards were within the USEPA's target risk range of 1×10^{-6} to 1×10^{-4}, or less than or equal to the hazard index of 1,with the exception of the future residential scenario. The ELCR for the hypothetical future resident exceeded 1×10^{-4} primarily due to the presence of benzo(a)pyrene in surface soils. The hazard index exceeded 1 for the hypothetical future resident due to potential exposure to the maximum concentration of cobalt in subsurface soil. However, it should be noted that with the exception of the single maximum detection of cobalt, all other cobalt detections were within established backgroundd levels for the

Building Debris Disposal Trench

RFAAP facility. Therefore, it is likely that the isolated elevated cobalt detection is related to natural conditions rather than historical activities at the BDDT or would pose a chronic heath hazard.

A SLERA and BERA were completed for the BDDT, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that adverse effects are not expected for wildlife at the BDDT.

Based on the results of the combined investigation activities completed at the BDDT between 1997 and 2008, the extent of soils affected by the former disposal activities at the site have been defined and delineated. The results from the 2008 sediment and surface water sampling event indicate that the residual PAHs present in the surface soils within the open area downslope of the BDDT are not resulting in continued releases of PAHs to the creek. The results of the HHRA and ERA indicate that potential risks associated with the site are within generally acceptable ranges for current and future industrial use of the site. However, elevated risks are present under the hypothetical residential land use scenario due to the presence of benzo(a)pyrene in soil under the rip rap covered portion of the site, as well as the downslope area. While the maximum concentration of cobalt at the BDDT also contributed to an elevated HI under the resident child exposure scenario, cobalt is not considered to be a real threat for hypothetical future residents or a driver for remediation. Based upon the location of the detection and the lack of cobalt in the ditch area, its presence is unlikely the result of disposal activities at the site and is likely naturally occurring.

Due to the potential residential risk associated with the benzo(a)pyrene in surface soil located downgradient of the trench and the soil located under the rip rap covered portions of the trench, it is recommended that a FS be conducted to evaluate the available CERCLA response actions for the site. The response action alternative analysis will include an evaluation of potential actions to reduce risk to levels acceptable for residential use of the property, as well as options for maintaining the industrial use of the property.

6. Bag Loading Area

6.1 Site Description and History

The BLA is located along the southwestern boundary of the RFAAP-NRU, to the south of the RY (Figure 1-2). The BLA ran two smokeless powder bag loading lines from 1941-1943. The propelling charge that was loaded in the bags consisted of smokeless powder and an igniter charge consisting of black powder. The bags loaded at the BLA were used for artillery, cannon, and mortar projectiles. A total of ten buildings were once located at the BLA. These buildings included those that were used for the loading operations, storage buildings, shipping and receiving buildings, as well as a changehouse/canteen. However, all process equipment, wooden roofs, and wooden walls have been removed from all of the buildings, leaving only concrete slabs and walls. The concrete slab floors in Buildings 404 through 413 (including the second story floors of Buildings 404 and 407) were covered in a conductive flooring material that contained various metals and asbestos. The BLA site layout depicting locations of building and conductive flooring is presented as Figure 6-1. This conductive flooring was used to prevent the build-up of static charges in areas where energetic materials were handled. Removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and break away from the underlying concrete. In some cases, the flooring has degraded into a red powder-like material and washed onto the surrounding soils. The concrete walls of these buildings were also painted with lead-based paint. Deterioration of the paint may have provided a potential source of lead to the soils immediately surrounding the former building areas. Buildings 414 through 416 were not utilized for handling the propellant materials and did not contain conductive flooring or concrete walls, and thus are not considered an environmental concern at BLA. Surface water at the BLA generally drains to the unnamed stream located to the north of the BLA via overland flow and through series of drainage ditches/culverts.

6.2 Physical Setting

Topography in the vicinity of the BLA buildings is generally flat. Vegetation is mostly limited to grass and small shrubs. Surface water is drained through a series of drainage ditches and culverts. Surface soil at the BLA consists of tan to dark brown silty clay and clay. The BLA is located on a hilltop and the soil is typical of the Lowell Silt Loam which forms from the weathering of limestone and interbedded shale. The Lowell Silt Loam is found on the hills and ridges throughout the NRU.

6.3 Conceptual Site Model

In accordance with the general CSM, presented in Section 3.5, potentially affected media at this site would include surface soil, subsurface soil, sediment, and surface water. Potential sources of adverse environmental effects at this site are historical manufacturing operations, deteriorating conductive flooring material, deteriorating lead based paint, and PCB containing electrical transformers that were formerly located at the site. It is also possible that residual asbestos containing materials (i.e., pipe insulation, mastic, joint compounds, etc.) are present in the BLA buildings that could be released to the environment, or could have been released during historic building demolition activities.

Surface soils in the areas surrounding the buildings with conductive flooring material appear to have the greatest potential to exhibit effects from historical operations and from the conductive flooring material. Surface soils located next to the buildings show signs of staining as a result of deteriorated conductive flooring material washing off of the building pads. Due to the composition of the flooring material, soils next to the buildings are expected to exhibit elevated concentrations of metals and asbestos. Soil sampling at the BLA has indicated that the COPCs at the site are generally confined to surface soils. Therefore, contaminant infiltration into subsurface soils does not appear to be a major pathway.

The majority of the BLA area is relatively flat, therefore erosion and/or migration of surface soils is expected to be fairly minimal. However, during heavy rainfall events surface water run-off has the potential to carry COPCs and affected soils to area drainage ditches which eventually direct the surface water to the unnamed creek that flows to the north of the BLA.

6.4 Environmental Investigations

The BLA was designated a Study Area for the RFAAP-NRU site due to the presence of deteriorating conductive flooring in site buildings that are composed of various inorganics and asbestos. In addition to the conductive flooring there were PCB-containing transformers at the site. The presence of these materials at the site warranted investigations of site media including soil surrounding building and former transformer locations, as well as sediment from drainage ditches in the vicinity of these locations. Environmental investigations at the BLA have been on-going since 1997 and have included:

- 1997 – Preliminary Sampling by Dames and Moore, Inc.
- 1997 and 1998 – Independent Sampling by Gannett Fleming
- 2002 – Conductive Flooring Assessment by USACE
- 2002 – Remedial Investigation by Shaw
- 2005 – Asbestos and Lead Investigation by Shaw
- 2008 – Remedial Investigation by ARCADIS
- 2009 – Supplemental Remedial Investigation by ARCADIS

The goals and findings of each of these investigations are summarized in the following sections. As discussed in Section 4.1, the constituent detections reported in these sections are discussed in terms relative to their medium specific screening criteria (i.e., RSLs), where applicable.

6.4.1 Preliminary Sampling, Dames and Moore, 1997

An initial December 1997 soil sampling effort was conducted by Dames and Moore, Inc. to provide an assessment of the lateral and vertical distribution of organic and inorganic constituents in soil around Buildings 407 at the BLA, resulting from the weathering of the conductive flooring. Three soil boring locations were positioned in a line perpendicular to the building at distances of 12, 36, and 60 inches from the building pad. Three samples were collected from depths of 0-1, 1-2, and 2-3 ft bgs at the location 12 inches away from the sidewalk. For the sampling locations 36 and 60 inches away from the sidewalk, two samples were collected at depths of 0-1 and 1-2 ft bgs. Sample identifications include the sample location code followed by the sample depth in parentheses. The following samples were collected during this investigation:

- Three surface soil samples (407712 (0-1), 407736 (0-1), and 407760 (0-1))
- Four subsurface soil samples (407712 (1-2), 407712 (2-3), 407736 (1-2), and 407760 (1-2))

All soil samples were analyzed for TAL inorganics. The laboratory analytical results for the soil samples are summarized in Table 6-1 and the sample locations are depicted in Figure 6-2. The results indicated the following:

Inorganics. Several inorganic constituents were detected in the surface and subsurface soil samples (see Table 6-1). With the exception of cobalt and aluminum, all of the detected constituents were below applicable RSLs and/or the established facility-wide background levels. Cobalt was detected in one subsurface soil sample [407712 (2-3 ft bgs)] at a concentration above the industrial RSL and slightly above background levels. Cobalt was not detected in any of the other subsurface or surface soil samples at concentrations above the established background level. Aluminum was also detected in subsurface soil sample 407712 (2-3) at a concentration between the residential soil and industrial soil RSLs and slightly above the established background level.

6.4.2 Independent Sampling, Gannett Fleming, 1997 and 1998

The objective of the independent sampling was to further characterize soil at the BLA. Initial investigation activities included the collection of one surface soil sample (SS-09) from the north side of Building 405 and one sample of the conductive flooring (WS-01) from Building 405. In 1998 two additional soil samples (SS-14 and TR-03E) were collected from areas northeast and northwest of Building 405 and two additional conductive flooring samples (WS-04 and WS-05) were collected. A total of three surface soil samples were collected and analyzed as follows:

- One surface soil sample for explosives and pesticides analysis (SS-09);
- Three surface soil samples for PCBs and SVOCs analysis (SS-09, SS-14, and TR-03E);
- Two surface soil samples for VOCs and TAL inorganics analysis (SS-09 and SS-14);

A total of three conductive flooring samples were collected and analyzed as follows:

- One conductive flooring sample for VOCs, SVOCs, PCBs, and pesticides analysis (WS-01);
- Three conductive flooring samples for TAL inorganics analysis (WS-01, WS-04 and WS-05)
- Two conductive flooring sample for asbestos analysis (WS-04 and WS-05)

The laboratory analytical results for soil and conductive flooring samples are summarized in Table 6-2 and 6-3, respectively. The sample locations are depicted in Figure 6-2.

6.4.2.1 Soil Sampling

The results of the soil sampling activities indicated the following:

Bag Loading Area

VOCs. One VOC (methylene chloride) was detected in two of the three soil samples (see Table 6-2). However, the detected concentrations were several orders of magnitude below applicable industrial and residential RSLs.

SVOCs. A total of 26 different SVOC constituents were detected in the surface soil samples collected during this phase of investigation as indicated in Table 6-2. However, benzo(a)pyrene at sample location SS-09 was the only constituent detected at a concentration above an applicable industrial RSL. Six other SVOC analytes [i.e., benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, dinitrotoluene mix, and indeno(1,2,3-cd)pyrene] were also detected in sample SS-09 at concentrations above residential RSLs. Benzo(a)pyrene was also detected in sample TR-03E at a concentration above the residential RSL. SVOCs were not detected above industrial or residential soil RSLs in any other soil samples.

PCBs. One PCB (Aroclor 1254) was detected in the soil samples (see Table 6-2). Aroclor 1254 was detected above the industrial RSL in sample SS-09. PCBs were not detected at concentrations above industrial or residential RSLs in any other soil samples.

Pesticides. Five different pesticides (4,4'DDD, alpha-chlordane, Endosulfan I, gamma-chlordane, and heptachlor epoxide) were detected in the soil sample collected at sample location SS-09 (see Table 6-2). The detected concentrations were all below applicable industrial and residential RSLs.

Explosives. One explosive constituent (2,4-dinitrotoluene) was detected at sample location SS-09. The detected concentration was below the reported industrial and residential soil RSL for 2,4-dinitrotoluene; however, the reported concentration was above the residential RSL for dinitrotoluene mix.

Inorganics. Several inorganic constituents were detected in the soil samples (see Table 6-2). However, copper and lead at sample location SS-09 were the only constituents detected at concentrations above applicable industrial RSLs and established background levels. Barium and zinc were also detected at sample location SS-09 at concentrations above the residential RSL and established background levels. No other inorganics were detected at concentrations above background and residential RSLs.

Bag Loading Area

6.4.2.2 Conductive Flooring Samples

VOCs. Two VOCs (acetone and methylene chloride) were detected in flooring sample WS-01 (see Table 6-3). The detected concentrations of both constituents were several orders of magnitude below applicable industrial and residential soil RSLs.

SVOCs. Seventeen different SVOC constituents were detected in flooring sample WS-01 (see Table 6-3 for complete list). Five of the SVOCs [Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Dibenzo(a,h)anthracene, and Indeno(1,2,3-cd)pyrene] were detected at concentrations above industrial RSLs. One SVOC, benzo(k)fluoranthene, was also detected at a concentration between the residential and industrial soil RSLs. The other SVOCs were all detected at concentrations below applicable industrial and residential RSLs.

PCBs. Aroclor 1254 was the only PCB detected in flooring sample WS-01 (see Table 6-3). The detected concentration of Aroclor 1254 (2.80 mg/kg) was above the industrial RSL of 0.74 mg/kg.

Pesticides. A total of eight pesticides were detected in flooring sample WS-01 (see Table 6-3). However, heptachlor epoxide was the only pesticide detected at a concentration above the industrial soil RSL. No other pesticides were detected at concentrations above respective industrial or residential soil RSLs.

Inorganics. Several inorganic constituents were detected in flooring samples WS-01, WS-04 and WS-05 (see Table 6-3). Copper was detected in all three samples at concentrations above industrial RSLs and established background levels. Barium, lead and zinc were also detected in flooring sample WS-01 at concentrations above background levels and residential RSLs; as was nickel in flooring sample WS-04.

Asbestos. Asbestos (Chrysotile) was detected in both conductive flooring samples WS-04 and WS-05 at a concentration of 1.6 percent. Sample WS01 was not analyzed for asbestos.

6.4.3 Conductive Flooring Assessment, USACE, 2002

The USACE completed a conductive flooring assessment in 2002 to further evaluate the composition of the conductive flooring material at the IAA and the BLA. The results of this investigation are summarized in the 2003 report entitled *Site Screening Report of Conductive Flooring at the Igniter Assembly Area and Bag Loading Area in the New*

Bag Loading Area

River Unit (USACE, 2003). The sampling activities at the BLA included the collection of flooring samples from three buildings (Buildings 405, 407 and 413).

Three conductive floor samples (one from each building) were collected from buildings in the BLA to verify floor material composition and assess transport and mobility. A small chunk of the red conductive flooring material was collected from the surface of the building foundation. The flooring appeared as a dry, dull red colored material containing white fibers. The samples were analyzed for TCL VOCs, TCL SVOCs, PCBs, TCL pesticides, explosives, inorganics, and asbestos. The laboratory analytical results are summarized in Table 6-4 and the sample locations are depicted in Figure 6-2. The results indicated the following:

VOCs. Methylene chloride was the only VOC detected in the three flooring samples (see Table 6-4). The detected concentrations were all below the residential soil RSL.

SVOCs. Two SVOCs [bis(2-Ethylhexyl)phthalate and Di-n-Butylphthalate] were detected in all three conductive flooring samples (see Table 6-4). The detected concentrations were all below residential soil RSLs.

PCBs. The PCB Aroclor 1254 was detected at concentrations below the residential RSL in three conductive flooring samples (see Table 6-4). No other PCBs were detected in any of the conductive flooring samples.

Pesticides. A total of four pesticides (4,4'DDE, 4,4'-DDT, dieldrin, and endrin) were detected in the flooring samples (see Table 6-4). The detected concentrations were all below applicable industrial and residential soil RSLs.

Explosives. Explosives were not detected in any of the conductive flooring samples (see Table 6-4).

Inorganics. Several inorganic constituents were detected in the conductive flooring samples (see Table 6-4). Copper was detected at concentrations above both industrial RSLs and established background concentrations in all three conductive flooring samples (RFAAP-405, RFAAP-407, and RFAAP-413). No other inorganics were detected at concentrations above industrial RSLs; however, cadmium and nickel were detected at concentrations above residential RSLs and background levels at samples RFAAP-413 and RFAAP-405, respectively.

Asbestos. The asbestos constituent chrysotile was detected in all three conductive flooring samples RFAAP-405, RFAAP-407, and RFAAP-413 at a concentration of 2 percent in each sample.

6.4.4 Remedial Investigation, Shaw 2002

The objective of the 2002 remedial investigation was to further characterize soil, sediment, and surface water at the BLA. This section is intended to provide a brief summary of the field activities conducted at the BLA by Shaw during the 2002 field investigation. The following samples were collected during this investigation:

- Eleven surface soil samples [BLASS01 (0-0.5) through BLASS11 (0-0.5)] were collected from areas adjacent to BLA buildings containing conductive flooring.
- Three additional soil borings (BLASB01 through BLASB03) were also advanced in the vicinity of buildings with conductive flooring material to collect both surface and subsurface soil samples.
- Three soil samples (BLATR01 through BLATR03) were collected from three former transformer locations.
- Two sediment samples (BLASD01 and BLASD02), were collected from dry stormwater drainage ditches that channel runoff from the BLA.
- Two co-located sediment (BLASD04 and BLASD05) and surface water (BLASW04 and BLASW05) samples were collected from the unnamed creek located to the north of the BLA buildings.

6.4.4.1 Soil Sampling

A total of 14 surface soil samples and three subsurface soil samples were collected next to the BLA buildings during the 2002 investigation. All of the soil samples were analyzed for TAL inorganics. Other analyte classes sampled for in this investigation included VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides, explosives, pH, and grain size; however, not all analytes were included at every location. The laboratory analytical results from this sampling event are summarized in Table 6-5 and the sample locations are depicted in Figure 6-2. The results indicated the following:

VOCs. Six VOCs (3-octanone, acetone, carbon disulfide, d-Limonene, tetrachloroethene, and toluene) were detected in a limited number of the soil samples during the 2002 investigation (see Table 6-5). The detected concentrations were all below applicable residential RSLs.

Bag Loading Area

SVOCs. A total of 25 SVOCs were detected in the soil samples collected during Shaw's 2002 investigation. A complete breakdown of the detected constituents is included in Table 6-5. The analytical results indicated that five of the SVOCs were detected at concentrations above industrial soil RSLs, including:

- Benzo(a)anthracene in two samples (BLASB02A and BLASB03A);
- Benzo(a)pyrene in eight samples (BLASB02A, BLASB03A, BLASS05, BLASS06, BLASS07, BLASS09, BLASS10, and BLASS11);
- Benzo(b)fluoranthene in three samples (BLASB02A, BLASB03A, and BLASS07);
- Dibenzo(a,h)anthracene in two samples (BLASB02A and BLASB03A); and
- Indeno(1,2,3-cd)pyrene in two samples (BLASB02A and BLASB03A).

Several SVOCs, including benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, 2,4-dinitrotoluene, and 2,6-dinitrotoluene were also detected in at least one soil sample at concentrations above applicable residential soil RSLs.

PAHs. A total of 17 PAHs were detected in the samples analyzed for PAHs (see Table 6-5). The analytical results indicated that no constituents were present at concentrations above industrial RSLs. Benzo(a)pyrene was detected at concentrations above the residential RSL in three surface soil samples (BLASB01, BLASS01, and BLASS02). No other PAHs were detected at concentrations above residential RSLs in any of the surface or subsurface soil samples.

PCBs. Aroclor 1254 was the only PCB detected in soil during the 2002 investigation (see Table 6-5). Aroclor 1254 was detected above the industrial RSL in one of the surface soil samples (BLASS01) located next to Building 405 and in one of the former transformer sample locations (BLATR02). PCBs were not detected at concentrations above industrial or residential RSLs in any other surface or subsurface soil samples during this phase of the investigation.

Pesticides. 4,4'-DDD and methoxychlor were the only pesticides detected in soil during this phase of investigation. Both constituents were only detected in individual samples and the reported concentrations were below applicable industrial and residential RSLs (See Table 6-5).

Herbicides. No herbicides were detected in any of the soil samples collected during this phase of investigation.

Bag Loading Area

Explosives. A total of nine different explosive constituents were detected in a limited number of surface soil samples collected adjacent to BLA buildings. The detected constituents and concentrations are outlined in Table 6-5. The concentrations of all of the detected constituents were below applicable residential and industrial RSLs; however, the cumulative concentration of 2,4-dinitrotoluene and 2,6-dinitrotoluene at sample location BLASS03 was above the industrial RSL for dinitrotoluene mix. These two constituents were also detected at sample location BLASS03 via the explosives laboratory analysis.

Inorganics. Several inorganic constituents were detected in all of the surface and subsurface soil samples collected during this phase of the investigation (see Table 6-5). Four inorganics were detected at concentrations above both industrial RSLs and established background concentrations in soil samples, including:

- Cobalt in one sample (BLASS11);
- Lead in three samples (BLASB03, BLASS03, and BLASS08);
- Manganese in one sample (BLASS11); and
- Mercury in one sample (BLASS03).

In addition to the above, the following six inorganics were detected at concentrations above residential RSLs and established background concentrations in soil samples, including:

- Aluminum in two samples (BLASB01B and BLASB02B);
- Barium in two samples (BLASB03A and BLASS03);
- Cadmium in three samples (BLASB03A, BLASS03, and BLASS08);
- Copper in seven samples (BLASB03A, BLASS03, BLASS05, BLASS06, BLASS07, BLASS08, BLASS09);
- Iron in one sample (BLASB01B); and
- Zinc in one sample (BLASS08).

6.4.4.2 Sediment Sampling

Two sediment samples (BLASD01 and BLASD02) were collected from BLA area drainage ditches during the 2002 investigation. The ditches were all dry during the sampling event and only carry water during heavy rainfall events. Two additional sediment samples (BLASD04 and BLASD05) were collected from the unnamed creek located to the north of the BLA buildings. The samples were analyzed for VOCs, PAHs/SVOCs, PCBs, pesticides, herbicides, explosives, and TAL inorganics. The laboratory analytical results from this sampling event are summarized in Table 6-6, and the sample locations are depicted in Figure 6-2. The results indicated the following:

VOCs. VOCs were not detected in any of the sediment samples (see Table 6-6).

SVOCs. Five SVOCs were detected between the four sediment samples [bis(2-ethylhexyl)phthalate, fluoranthene, phenanthrene, pyrene, and benzoic acid]. As presented in Table 6-6, all of the detected concentrations were below applicable residential and industrial RSLs.

PAHs. A total of sixteen PAHs were detected between the four sediment samples (see Table 6-6). The detected concentrations were all below applicable residential and industrial RSLs.

PCBs. PCBs were not detected in any of the sediment samples (see Table 6-6).

Pesticides. A total of 11 different pesticides were detected between the four sediment samples included in this event. These constituents, and their detected concentrations, are outlined in Table 6-6. The detected concentrations were all below applicable industrial and residential RSLs. .

Herbicides. Herbicides were not detected in any of the sediment samples (see Table 6-6).

Explosives. Explosives were not detected in any of the sediment samples (see Table 6-6).

Inorganics. Several inorganic constituents were detected in all of the sediment samples (see Table 6-6); however, all of the detected concentrations were below applicable RSLs (residential and industrial) and/or established background levels.

6.4.4.3 Surface Water Sampling

Two surface water samples (BLASW04 and BLASW05) were collected from the unnamed creek located to the north of the BLA buildings. The laboratory analytical results from the surface water samples are summarized in Table 6-7, and the sample locations are depicted in Figure 6-2. The results indicated the following:

VOCs. Carbon disulfide and chloroform were the only VOCs detected in the surface water samples from the unnamed creek. The detected concentrations were lower than the tap water RSLs (see Table 6-7).

SVOCs. Butylbenzylphthalate and di-n-butylphthalate were the only SVOCs detected in the surface water samples (see Table 6-7). The detected concentrations of these constituents were lower than tap water RSLs.

PAHs. PAHs were not detected in either of the surface water samples.

PCBs. PCBs were not detected in either of the surface water samples.

Pesticides: Dieldrin was the only pesticide detected in the surface water samples (see Table 6-7). The detected concentration of dieldrin in surface water sample BLASW05 was higher than the tap water RSL. It should be noted that during this sampling event, dieldrin was also detected at a concentration above the tap water RSL in an upstream surface water sample collected for the WBG (see Table 9-11). This sample (WBGSW14) was collected upstream of where the stream first enters the RFAAP-NRU indicating a potential off-site source.

Herbicides. 2,4-D was detected on one surface water sample (BLASW04) during this sampling event (see Table 6-7). The detected concentration was several orders of magnitude below the tap water RSL.

Explosives. m-Nitrotoluene was detected in both of the surface water samples during this event (see Table 6-7). There is not an established tap water RSL for this constituent. No other explosives were detected in the surface water samples.

Inorganics. Several inorganics were detected in both of the surface water samples (see Table 6-7). However, the detected concentrations were all lower than established tap water RSLs.

6.4.5 Asbestos and Lead Investigation, Shaw, 2005.

Shaw completed an asbestos and lead based paint survey at the BLA during 2005. This event included the collection of the following samples:

- Six soil samples (BLASS12 through BLASS17) were collected for asbestos analysis

Bag Loading Area

- Two samples of deteriorated conductive flooring material (BLADF01 and BLADF02) were collected for asbestos analysis
- Two samples of intact conductive flooring (BLAIF01, and BLAIF02) were collected for asbestos analysis
- Three wipe samples (BLAW01, BLAW02 and WB01) for asbestos analysis
- One paint chip sample (BLAPC01) from BLA Building 405 for lead analysis

The exact locations of the samples collected during this investigation were not recorded by Shaw. According to a February 2005 Draft Field Sampling Plan, three soil samples would be collected adjacent to each of two previous sample locations (BLASB03 and BLASS03), flooring and wipe samples would be collected from Buildings 404 and 405 adjacent to previous soil samples BLASB03 and BLASS03 and a paint chip sample would be collected from Building 405 adjacent to previous soil sample BLASS03. The laboratory analytical results for the soil samples, conductive flooring samples, wipe samples, and paint chip sample are presented in Table 6-8.

The results of the asbestos analysis indicated that the chrysotile was the only asbestos type detected. Total asbestos concentrations detected in the soil samples ranged from 3.2 to 14.2%. Asbestos concentrations in the intact flooring material ranged from 16.5 to 20.8% and from 10.5% to 11.3% in the deteriorated flooring. Asbestos was detected at a concentration ranging from 2,820 to 225,000,000 structures per cm^2 (s/cm^2) in the three wipe samples collected from red-stained walls.

The results from the paint chip sample indicated that the lead concentration was 306 mg/kg. Very little paint remains on the BLA buildings.

6.4.6 RI Investigation, ARCADIS 2008

In accordance with Remedial Investigation Work Plan Addendum 27 (ARCADIS 2008b), ARCADIS completed additional investigation activities at the BLA in 2008 to finalize the characterization and delineation work at this site. The primary goal of the 2008 investigation was to complete the delineation of inorganics, PAHs, and asbestos in surface soils around buildings containing conductive flooring. The investigation also included the collection of soil samples to delineate historical PCB and PAH detections at previous transformer locations near Buildings 405 and 416, and lead detections in sediments from area drainage pathways. One ponded water sample was collected from an elevator shaft in Building 405 and one water sample was also collected from a utility vault below Building 405. The investigation activities and results for these areas are discussed in the following sections.

Bag Loading Area

6.4.6.1 2008 Building Area Inorganics and Asbestos Investigation

The primary goal of ARCADIS' 2008 investigation was to delineate the extent of PAHs, inorganics, and asbestos detections in surface soil surrounding buildings with conductive flooring material. Following is a summary of the investigation activities performed to complete this assessment:

- ARCADIS performed an inventory of the buildings at the BLA to identify buildings with conductive flooring, including those that may not have appeared on historic site maps. The locations of all buildings were surveyed utilizing GPS equipment and measurements were collected of the building dimensions. All buildings at the BLA are depicted in Figure 6-1. The building inventory identified seven buildings with conductive flooring material. In total approximately 19,000 ft^2 of conductive flooring material is present at the site.

- Review of the analytical data collected during the previous investigations of the BLA indicated that lead could be used as a good predictor of where other constituents may also be present in surface soil at concentrations above applicable screening criteria as a result of the deteriorating conductive flooring. Therefore, ARCADIS developed a field screening program that utilized a hand-held X-Ray Fluorescence (XRF) meter to screen surface soil samples for lead. Samples were typically collected in rows of three screening points spaced at 1 ft, 5 ft, and 10ft distances from the building footprint. In cases where the XRF result indicated a lead concentration above 400 mg/kg, the samples were also collected further away from the building (i.e., 15 ft and 20 ft). The rows were located on approximately 25 ft centers around the perimeter of each building, with a bias towards preferential flow paths off of the building pads (i.e., where red staining was present in soil). A total of 63 rows containing 192 individual points (BLA-R1A through BLA-R63C) were screened with the XRF around the perimeters of buildings identified with conductive flooring. The field screening locations are depicted in Figure 6-3. The screening points were identified with the letter R for Row followed by a number (001 through 63) representing the row number where the screening point was located, followed by a letter (A, B, C, or D) representing the distance from the building pad to the sample location (1, 5, 10, 15ft, respectively).

- In order to evaluate the results of the XRF screening results and to provide additional characterization data, samples for laboratory analysis were collected from 19 of the 192 XRF screening locations. A minimum of one sample was collected at each building identified with conductive flooring. These samples (BLA-SS001 through BLA-SS019) were submitted for laboratory analysis of TAL inorganics, SVOCs, and asbestos. Five of these samples (BLA-SS003, BLA-SS008, BLA-SS010, BLA-SS017, and BLA-SS019) were also submitted for laboratory analysis of TCLP-inorganics. The sample locations are depicted in Figure 6-2.

6.4.6.2 XRF Lead Screening Results

The results of the XRF lead screening activities at the BLA buildings are summarized in Table 6-9. The locations and results of the XRF screening are also presented in Figure 6-3. The XRF screening activities indicated the following:

- The XRF screening results indicated that lead concentrations were above industrial RSL in 30 of the 192 field screening locations. In addition, there were 20 locations where the detected lead concentrations were between the residential and industrial RSL. Figure 6-4 illustrates the distribution of the detected lead concentrations during the XRF field screening program. All of the screening locations that had lead concentrations above the RSLs occurred at four site buildings (Buildings 404, 405, 406, and 407) located in the central portion of the BLA. Field observations indicated that these buildings were surrounded by a significant amount of gravel debris that may have influenced the XRF results. The XRF screening results at Buildings 411, 412, and 413 were all below the residential RSL.

- Following is a summary of the XRF detected lead concentrations at each of the BLA buildings:

    - **Building 404 –** 14 of 65 screening locations at Building 404 had lead detections above the industrial RSL. The detected lead concentrations in these samples, ten of which were collected 1-ft away from the building pad, three at 5 ft and one at 10 ft, ranged from 773 mg/kg to 4,640 mg/kg. All but two of the screening points above the industrial RSL were located on the southern and eastern sides of Building 404. Nine locations at Building 404 had lead detections between the residential and industrial RSLs. The detections above the residential RSL extended up to 15-ft from the building pad in one location on the south side of the building. See Table 6-9 for a complete summary of the XRF results.

- **Building 405** – Six of 58 screening locations at Building 405 had lead detections above the industrial RSL. The detected lead concentrations in these samples, four of which were collected 1-ft away from the building pad, one at 5 ft and one at 10 ft, ranged from 808 mg/kg to 1,294 mg/kg. All of the six screening points above the industrial RSL were located on the northern and eastern sides of Building 405. Eight locations at Building 404 had lead detections between the residential and industrial RSLs. See Table 6-9 for a complete summary of the XRF results.

- **Building 406** – Building 406 is a small building located to the west of Building 404 in the southern portion of the BLA. Five of the six screening locations at Building 406 had lead detections above the industrial RSL. The detected lead concentrations in these samples, two of which were collected 1-ft away from the building pad, two at 5 ft and one at 10 ft, ranged from 1,940 mg/kg to 12,799 mg/kg. One screening point at Building 406 had lead detections between the residential and industrial RSLs. All screening points were located on the southeast and southwest sides of the building. See Table 6-9 for a complete summary of the XRF results.

- **Building 407** – Building 407 is a small building located to the west of Building 405 in the northern portion of the BLA. Like Building 406, many of the XRF readings collected around this building were elevated in comparison to other areas of the site. Five of the seven screening locations resulted in lead concentrations above the industrial RSL. The detected lead concentrations in these samples, two of which were collected 1-ft away from the building pad, two at 5 ft and one at 10 ft, ranged from 2,055 mg/kg to 12,843 mg/kg. The other two screening points contained lead concentrations below residential soils RSLs at 10 and 15 ft from the building. The detections above the industrial RSL were confined to soils within five to ten ft of the building pad. See Table 6-9 for a complete summary of the XRF results.

- **Buildings 411, 412, and 413** – Buildings 411, 412, and 413 are located in the western portion of the BLA. All screening locations at these three buildings had reported lead concentrations below the residential RSL. See Table 6-9 for a complete summary of the XRF results.

Bag Loading Area

6.4.6.3 BLA Inorganics and Asbestos Sampling

ARCADIS collected soil samples at 19 of the 192 XRF field screening locations to evaluate the results of the XRF field screening and to provide additional characterization of the surface soils. At least one sample was collected at each of the seven conductive flooring buildings at the BLA. These samples (BLA-SS001 through BLA-SS019) were submitted for laboratory analysis of TAL inorganics and asbestos. The sample locations are depicted in Figure 6-2, and the laboratory analytical results are summarized in Table 6-10. The laboratory analytical reports for the 2008 sampling activities are included in Appendix D**.** The laboratory analytical results indicated the following:

- Lead was the inorganic most frequently detected inorganic at concentrations above the industrial soil RSLs and established background concentrations. Lead was detected at concentrations above the industrial RSL in 10 of the 19 samples, and between the residential and industrial RSLs in 2 other samples (see Table 6-10). The maximum lead concentration (58,000 mg/kg) was detected in sample BLA-SS013 located 1-ft away from Building 406. Of the ten samples at concentrations above industrial soil RSLs, eight were located 1-ft from the building pads (Buildings 404 through 407), one was located 5-ft and one located 10-ft from building pads. Figure 6-5 illustrates the distribution of the lead concentrations detected in the laboratory samples during the 2008 sampling event.

- In general, the detected lead concentrations were very comparable with the XRF readings; although, the XRF readings were typically biased slightly high compared to the laboratory detected concentration. These data indicate that the XRF field analysis was a good screening tool for identifying areas with lead concentrations above applicable RSLs. See Table 6-10 for comparison between the XRF screening results and the laboratory analytical results. Figure 6-6 also presents a graphical comparison of the XRF and laboratory lead results.

- Arsenic was detected above the established background concentration (15.8 mg/kg) and above the industrial RSL (1.6 mg/kg) in 2 of the 19 soil samples collected in 2008 from the BLA (see Table 6-10). The two samples with lead concentrations above the industrial RSL were collected at 1-foot distance from Buildings 404 and 406. The maximum arsenic concentration (47.2 mg/kg) was detected in sample BLA-SS014 located adjacent to Building 404.

Bag Loading Area

- Barium was not detected above the industrial soil RSL (190,000 mg/kg) in any samples, but was detected above the established background concentration (209 mg/kg) and above the residential soil RSL (1,500 mg/kg) in seven of the 19 soil samples collected in 2008 from the BLA (see Table 6-10). The maximum barium concentration (11,100 mg/kg) was detected in sample BLA-SS008 located 1-ft from Building 405. Five of the seven samples with lead concentrations above residential RSL were collected at 1-foot distance from Buildings 404 and 405, while one was collected 5 ft and one collected 10 ft from Building 405.

- Cadmium was detected above the established background concentration (0.69 mg/kg) and above the residential soil RSL (7 mg/kg) in seven of the 19 soil samples collected in 2008 from the BLA (see Table 6-10); however, cadmium was not detected above the industrial soil RSL (81 mg/kg) in any samples. The maximum cadmium concentration (44.8 mg/kg) was detected in sample BLA-SS013 located adjacent to Building 406. Five of the seven samples with cadmium concentrations above residential RSL were collected at 1-ft distance from Buildings 404, 405, and 406, while one was collected 5 ft and one collected 10 ft from Building 405.

- Copper was detected above the established background concentration (53.5 mg/kg) and above the industrial soil RSL (4,100 mg/kg) in five of the 19 samples collected in 2008 from the BLA (see Table 6-10). In addition, copper was detected between the residential and industrial soil RSLs in eight other samples. The maximum copper concentration (72,000 mg/kg) was detected in sample BLA-SS013 located 1 ft from Building 406. Of the 13 samples with copper concentrations above residential or industrial RSLs, nine were located at 1 ft, three at 5 ft and one at 10 ft distance from Buildings 404, 405, 406 and 407.

- Iron was detected above the established background concentration (50,962 mg/kg) and above the residential soil RSL (5,500 mg/kg) in two of the 19 soil samples collected in 2008 from the BLA, but was not detected above the industrial soil RSL (720,000 mg/kg) in any samples (see Table 6-10). The maximum iron concentration (61,500 mg/kg) was detected in sample BLA-SS012 located 5 ft distance from Building 405. The other sample with iron concentration above the residential RSL was located 5 ft distance from Building 412, which had no other inorganics at concentrations above both residential RSLs and established background concentrations.

Bag Loading Area

- Mercury was detected above the established background concentration (0.13 mg/kg) and above the residential and industrial soil RSL (3.1 mg/kg, each) in two of the 19 soil samples collected in 2008 from the BLA (see Table 6-10). The two samples with mercury concentrations above RSLs were collected at 1 ft distance from Buildings 404 and 405.

- Zinc was detected above the site-wide natural background concentration (202 mg/kg) and above the residential soil RSL (2,300 mg/kg) in six of the 19 soil samples collected in 2008 from the BLA (see Table 6-10); however, zinc was not detected above the industrial soil RSL (310,000 mg/kg) in any samples. The maximum zinc concentration (12,500 mg/kg) was detected in sample BLA-SS013 located 1 ft distance from Building 406. Of the six samples with zinc concentrations above residential RSLs, five were located at 1 ft distance and one at 5 ft distance from Buildings 404, 405, and 406.

- Asbestos was detected in all 19 of the surface soil samples collected at the BLA in 2008 (see Table 6-10). These samples were generally collected from sample locations where XRF screening and laboratory analytical results also indicated the presence of elevated metals.

- TCLP analysis of soil samples collected in 2008 indicated that no inorganics were present in soil at concentrations above TCLP disposal standards (see Table 6-10).

6.4.6.4 BLA PAH Sampling

Each of the 19 soil samples (BLA-SS001 through BLA-SS019) collected adjacent to BLA buildings containing conductive flooring were also submitted for laboratory analysis of PAHs. Four additional samples (BLA-SS005 through BLA-SS008) collected from the central area of the BLA were also analyzed for PAHs. The sample locations are depicted in Figure 6-2, and the laboratory analytical results are summarized in Table 6-10. The laboratory analytical reports for the 2008 sampling activities are included in Appendix D. The laboratory analytical results indicated the following:

Central BLA Area

ARCADIS collected four surface soil samples surrounding the location of a sample collected near the center of the BLA in 2002 (BLASB02) that contained PAHs above

Bag Loading Area

industrial RSLs. Laboratory analytical results from the four surface soil samples collected near the center of the BLA indicated that five PAHs were detected at concentrations above the industrial soil RSLs, including: Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Dibenzo(a,h)anthracene, and Indeno(1,2,3-cd)pyrene. One PAH constituent (Benzo(k)fluoranthene) was also detected in all four samples at a concentration between the residential and industrial RSLs.

BLA Conductive Flooring Buildings

Laboratory analytical results from the 19 surface soil samples collected in the vicinity of the BLA conductive flooring buildings indicated that six PAHs were detected at concentrations above the industrial soil RSLs, including:

- Benzo(a)anthracene in four soil samples (BLA-SS005, BLA-SS007, BLA-SS009, and BLA-SS017)
- Benzo(a)pyrene in 14 soil samples (BLA-SS001, BLA-SS004, BLA-SS005, BLA-SS007, BLA-SS009, BLA-SS010, BLA-SS011, BLA-SS012, BLA-SS013, BLA-SS014, BLA-SS016, BLA-SS017, BLA-SS018, and BLA-SS019)
- Benzo(b)fluoranthene in five soil samples (BLA-SS005, BLA-SS007, BLA-SS009, BLA-SS010, and BLA-SS017)
- Benzo(k)fluoranthene in one soil sample (BLA-SS005)
- Dibenzo(a,h)anthracene in seven soil samples (BLA-SS001, BLA-SS005, BLA-SS007, BLA-SS009, BLA-SS010, BLA-SS017, and BLA-SS018), and
- Indeno(1,2,3-cd)pyrene in three samples (BLA-SS005, BLA-SS009, and BLA-SS017)

These six PAH constituents plus Chrysene were also detected at concentrations between the residential and industrial soil RSLs in many of the soil samples collected in the vicinity of the BLA buildings with conductive flooring. PAHs appeared to be present equally in samples collected at distances 1 ft, 5 ft, and 10 ft from the buildings.

6.4.6.5 Former Transformer Area Sampling

The analytical results from samples collected north of Building 405 in 2002 (BLASS01) indicated that Aroclor 1254 was present in surface soil at concentrations above the industrial RSL. Additionally, sample BLATR02 collected in 2002 at the location of a former transformer east of Building 416 also contained Aroclor 1254 at a concentration above the industrial RSL. In order to complete the delineation of these two areas,

Bag Loading Area

ARCADIS collected two surface soil samples (BLASS001 and BLASS002) and two subsurface soil samples [BLA-SB001 (1-2), and BLA-SB001 (2-3)] near 2002 sample BLASS01 and two surface soil samples (BLA-SS003 and BLA-SS004) near the 2002 IBLATR02 sample location (see sample locations in Figure 6-2). The surface and subsurface samples were analyzed for PCBs. The analytical results from these samples are summarized in Table 6-10. The results indicated that PCBs were not detected above residential RSLs in any of the soil samples.

6.4.6.6 Utility Vault and Elevator Shaft Water Samples

Underground, concrete, utility vaults were identified at Buildings 404 and 405 that appear to extend around the perimeter of the buildings. Standing water was present in the vaults with a depth of approximately 1 ft. No sediment was visible at the bottom of the vaults. A sample of the vault water (BLA-VLTW01) was collected from the Building 405 vault for laboratory analysis of VOCs, PAHs, and TAL metals (see Figure 6-2 for sample location).

Ponded water along with sediment material were also observed at the base of an elevator shaft in Building 405. A sample of the ponded water (BLA-SPSW01) was collected from the elevator shaft for analysis of PAHs and TAL metals (see Figure 6-2 for sample location). The analytical results from the ponded water sample are summarized in Table 6-11. The ponded water results indicated that no constituents were detected at concentrations above tap water RSLs except for arsenic which was detected at concentrations within expected background levels.

6.4.6.7 Elevator Shaft Sediment Samples

Sediment material was observed at the base of an elevator shaft in Building 405 along with the ponded water discussed above. This material appeared to be composed of degraded flooring material along with soil and miscellaneous debris. A sample of the sediment material (BLA-SPSD01) was collected from the elevator shaft for analysis of PAHs and TAL metals (see Figure 6-2 for sample location). The analytical results are summarized in Table 6-12. The results indicated the following:

PAHs. Seventeen different PAHs were detected in the elevator shaft sediment sample (see Table 6-12). Three of the PAHs [benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene] were detected at concentrations above industrial soil RSLs. Two other PAHs [Benzo(a)anthracene and Indeno(1,2,3-cd)pyrene] were also detected at concentrations between residential and industrial soil RSLs. No other PAHs were detected above residential soil RSLs.

Inorganics. Several inorganics were detected in the elevator shaft sediment samples (see Table 6-12). None of the detected constituents were detected at concentrations above both industrial soil RSLs and established background concentrations. However, copper was detected at a concentration above the established background concentration and the residential soil RSL. Copper is known to be a major component of the degrading conductive flooring material in Building 405. No other inorganics were detected at concentrations above both the established background concentrations and residential soil RSLs.

6.4.7 Supplemental RI Investigation, ARCADIS 2009

In accordance with the June 2009 Supplemental Remedial Investigation Work Plan (ARCADIS 2009b), ARCADIS completed additional investigation activities at the BLA in 2009. The goals of the 2009 investigation were to: 1) enhance the delineation of asbestos in surface soils around buildings containing conductive flooring; and 2) to evaluate potential airborne asbestos exposure risks associated with the asbestos in soil. Both soil and air samples were collected and analyzed for asbestos during this investigation. The investigation activities and results for these areas are discussed in the following sections.

6.4.7.1 Asbestos Delineation Sampling

ARCADIS' 2008 sampling activities at the BLA indicated that asbestos was present in surface soil adjacent to buildings with conductive flooring. However, the analytical method utilized during the 2008 event was only able to provide a qualitative evaluation of whether or not asbestos fibers were present in the samples. In order to conduct a quantitative risk evaluation of asbestos in surface soil, and to further define how far the asbestos extends from the buildings, ARCADIS collected additional soil samples from the site in 2009. These surface soil samples were collected at locations where asbestos was detected during the 2008 sampling event and where there was visible evidence that degraded flooring material has washed off of the building pads. The samples were collected at step out distances of 1 ft, 5 ft, 10 ft, 15 ft, and 20 ft from the building at each sample location. A total of 10 rows of samples were collected for this evaluation (BLA-SS020 through BLA-SS029) and a minimum of one row of samples was collected at each of the seven BLA Buildings with conductive flooring. Note that the suffixes A, B, C, D, and E were used to designate whether the sample was

Bag Loading Area

collected 1, 5, 10, 15, or 20 ft from the building, respectively. The samples were analyzed for asbestos by TEM CARB Level B in sequence by distance from building until the reported concentration was at or below 0.1% by weight. Once concentrations were at or below this level, samples that were collected at further distances were not analyzed. The sample locations from the 2009 investigation are depicted in Figure 6-2 and the analytical results are summarized in Table 6-13. The laboratory analytical reports are presented in Appendix D. The analytical results from the delineation sampling indicated the following:

- Asbestos fibers were detected in all of the analyzed samples. However, the detected concentrations were less than 0.1% asbestos by weight in 11 of the 19 analyzed samples. Only one sample (9.4 % at BLA-SS026A) had a reported asbestos concentration greater than 0.2%. This sample was collected 1-ft from Building 406. The sample collected 5 ft from Building 406 (BLA-SS026B) had a reported concentration of <0.1%, indicating that the asbestos is limited to the soil immediately adjacent to the building.

- Chrysotile was the only asbestos type detected in the 18 of the 19 analyzed soil samples. The only other asbestos type detected was crocidolite; one fiber of which was detected in soil sample BLA-SS023C. This sample was collected 10 ft from Building 405 and the total asbestos concentration at this sample was 0.1%.

6.4.7.2 Activity Based Sampling

In an effort to facilitate an evaluation of the potential risk of exposure to airborne asbestos fibers resulting from asbestos in soil, ARCADIS conducted an activity based sampling program at two of the BLA buildings where asbestos had historically been detected in soil (Buildings 404 and 411). This sampling program, which utilized the USEPA recommended generic action scenario of raking, was performed in accordance with USEPA *SOP 2094: Activity-Based Air Sampling for Asbestos* (USEPA, 2007c) and *Framework for Investigating Asbestos-Contaminated Superfund Sites* (USEPA, 2008g). The following subsections discuss the sample locations and analytical results.

6.4.7.2.1 Sample Locations

Buildings 404 and 411 were selected for the 2009 activity based sampling programs based on the presence of asbestos detections during the 2008 sampling event and visible evidence of conductive flooring material having washed off the building pads

Bag Loading Area

onto surrounding soils. The following sample locations were established at each building:

- Two 10 ft by 10 ft sample grids were set up near the southwest corner of Building 404 in an area that has had historic asbestos detections. The first grid was located 0-10 ft from the edge of the building pad. The second grid was located adjacent to the first, but at a distance of 10-20 ft from the edge of the building. The grid locations are depicted in Figure 6-2.

- Two 10 ft by 10 ft sample grids were also established at the southwest corner of Building 411. Like at Building 404, the first grid was located 0-10 ft from the edge of the building and the second grid was located 10-20 ft from the building. The grid locations are depicted in Figure 6-2.

- Soil samples were collected from the centerline of each sampling grid pair at both buildings. The samples were collected at distances of 1, 5, 10, 15, and 20 feet from Building 404 (BLA404-SS001A through BLA404-SS001E) and Building 411 (BLA411-SS001A through BLA411-SS001E). These samples were collected from a depth of 0-3 inches. The samples were analyzed for soil moisture by ASTM Method D2216-05, grain size by ASTM Method D6913-04e, and asbestos by TEM CARB Level B) to establish soil conditions and asbestos levels in the soil within the grids. The analytical results for the soil samples are presented in Table 6-13. The laboratory analytical reports are presented in Appendix D.

6.4.7.2.2 Activity Based Sampling Technique

This section presents a brief discussion of the sampling technique for the activity based sampling activities.

- Starting at the grid located furthest from Building 404, each 10ft by 10 ft grid was vigorously raked by a participant wearing Level C person protection equipment to simulate an aggressive soil disturbance activity. During the raking activity, the participant wore a personal air monitoring pump fitted with a 0.8 µm mixed cellulose ester (MCE) filter and sampling tube mounted in the subjects breathing zone. A stationary air monitoring pump fitted with a 0.8µm filter and sampling tube mounted at a height of 5 feet was also set on the downwind perimeter of the grid to collect air samples during the raking activity. The raking activity was performed for a duration that allowed a minimum of

750 to 1,000 liters of air to be pulled through each filter (approximately 2 hours).

- The personal air monitoring pump samples collected at each grid were identified as follows:
    - Building 404, 0-10 ft Grid: BLA404-AA1
    - Building 404, 10-20 ft Grid: BLA404-AA2
    - Building 411, 0-10 ft Grid: BLA411-AA1
    - Building 411, 10-20 ft Grid: BLA411-AA2

- The stationary perimeter air monitoring pump samples collected at each grid were identified as follows:
    - Building 404, 0-10 ft Grid: BLA404-AP1
    - Building 404, 10-20 ft Grid: BLA404-AP2
    - Building 411, 0-10 ft Grid: BLA411-AP1
    - Building 411, 10-20 ft Grid: BLA411-AP2

- In addition to the air samples collected at the sample grids, background air samples were collected near Building 404 and 411 to evaluate the potential for background interferences. Stationary air monitoring pumps were set up at upwind locations at both buildings in a fashion similar to the stationary air monitoring pumps at the sampling grids. The background sample at Buildings 404 and 411 were labeled BLA404-BK2 and BLA411-BK1, respectively.

- All of the personal air monitoring pump samples, stationary perimeter pump samples, and background samples were submitted for laboratory analysis of asbestos by TEM Method 10312. The analytical results for all of the air samples are presented in Table 6-14. The laboratory analytical reports are presented in Appendix D. The analytical results from the TEM Method 10312 report the asbestos concentrations in air using several different methods, including: 1) the Asbestos Hazard Emergency Response Act (AHERA) counting method; 2) Phase Contrast Microscopy- equivalents (PCME); 3) Berman Crump Protocol Structures (BCPS) (i.e. structures that are greater than 10 µm long and less than or equal to 0.4 µm in width); and 4) total structures by Transmission Electron Microscopy (TEM).

Bag Loading Area

6.4.7.2.3 Laboratory Analytical Results

This subsection presents a summary of the analytical results from the 2009 activity based sampling areas:

- **Building 404 Soil Samples:** Asbestos concentrations in soil ranged from 0.2% asbestos by weight at 1 ft from the edge of the building to <0.1% asbestos in the samples collected 5, 10, 15, and 20 ft from the Building 404. Chrysotile was the only type of asbestos present in the samples. Although not sampled, it should be noted that red staining from the degraded flooring material was observed in soil located approx 0-8 inches from the edge of Building 404.

- **Building 404 Personal Air Monitoring Pump Samples:** No asbestos fibers were detected in the personal air monitoring pump sample collected in the grid located 10-20 ft from the edge of Building 404 (BLA404-AA2). Asbestos was detected in the personal air monitoring pump sample collected from the grid located 0-10 ft from Building 404 (BLA404-AA1). The results indicated that all of the detected fibers were chrysotile. The asbestos concentrations reported via the various counting methods ranged from 0.0019 structures per cubic centimeter (s/cc) using PCME to 0.022 s/cc using TEM.

- **Building 404 Perimeter Air Monitoring Pump Samples:** No asbestos fibers were detected in the perimeter air monitoring pump sample collected from the grid located 10-20 ft from the edge of Building 404 (BLA404-AP2). Asbestos was detected in the perimeter air monitoring pump sample collected 0-10 ft from Building 404 (BLA404-AP1). The results indicated that all of the detected fibers were chrysotile. The asbestos concentrations reported via the various counting methods ranged from 0.0018 s/cc using PCME to 0.090 s/cc using TEM.

- **Building 404 Background Air Monitoring Pump Sample:** No asbestos fibers were detected in the background air monitoring sample from Building 404 (BKG404-BK2).

- **Building 411 Soil**: Asbestos concentrations in soil ranged from <0.1 % to 0.6% asbestos by weight. Chrysotile was the only type of asbestos present in the samples. Although not sampled, it should be noted that red staining from the degraded flooring material was observed in soil located approx 0-6 inches from the edge of Building 411.

- **Building 411 Personal Air Monitoring Pump Samples:** No asbestos fibers were detected in the personal air monitoring pump sample collected in the grid located 10-20 ft from the edge of Building 411 (BLA411-AA2). Asbestos was detected in the personal air monitoring pump sample collected from the grid located 0-10 ft from Building 411 (BLA411-AA1). The results indicated that all of the detected fibers were chrysotile. The asbestos concentrations reported via the various counting methods ranged from 0.014 s/cc using PCME to 0.078 s/cc using TEM.

- **Building 411 Perimeter Air Monitoring Pump Samples:** No asbestos fibers were detected in the perimeter air monitoring pump sample collected from the grid located 10-20 ft from the edge of Building 411 (BLA411-AP2). Asbestos was detected in the perimeter air monitoring pump sample collected 0-10 ft from Building 411 (BLA411-AP1). The results indicated that all of the detected fibers were chrysotile. The asbestos concentrations reported via the various counting methods were all the same, 0.034 s/cc.

- **Building 411 Background Air Monitoring Pump Sample:** No asbestos fibers were detected in the background air monitoring sample from Building 411 (BKG-411BK1).

6.5 Nature and Extent of Constituent Detections

The analytical results presented in the previous sections indicate that constituents have been detected at concentrations above applicable screening criteria at the BLA. The majority of the detections appear to be the result of degrading conductive flooring material in site buildings. Areas that have been investigated at the BLA include: soil surrounding all buildings that contain conductive flooring, soil surrounding the locations of former transformers, sediment from drainage ditches in the vicinity of buildings that contain conductive flooring, ponded water from within a subsurface concrete vault adjacent to Building 522, surface water and sediment from a small unnamed stream located to the north of the BLA buildings, and building materials, including conductive flooring and paint samples.

6.5.1 Soil

6.5.1.1 Building Area Assessment

The primary focus of the environmental investigations at the BLA was to identify potential adverse affects to soil quality as a result of historical operations at the site and from degrading flooring material in site buildings. To this affect, approximately 57 surface soil samples and 9 subsurface soil samples were collected around the various BLA buildings between 1997 and 2008. A total of 192 surface soil samples were also collected around the BLA buildings for lead field screening using XRF. During 2009 approximately 29 additional surface soil samples and 10 air filter samples were collected for an activity based sampling effort designed to evaluate potential risks associated with asbestos in surface soil. Site maps depicting the inorganic constituents detected in soil samples during the BLA investigation are presented in Figure 6-7. Figure 6-8 displays the organic constituents that were detected in the soil samples. Figure 6-9 displays the results of the 2009 asbestos investigation. Figure 6-3 displays the results of the 2008 XRF field screening activities.

As illustrated by the figures, the results of the investigation activities indicated the following:

- No VOCs, pesticides, or herbicides were detected in surface soil or subsurface soil samples at concentrations above residential RSLs.

- Dinitrotoluene Mix was the only explosive detected above residential soil RSLs. Historical samples SS-09 and BLASS03 contained Dinitrotoluene Mix above the residential and industrial soil RSLs, respectively. Both samples were adjacent to Building 405.

- Aroclor 1254 was the only PCBs detected in soil at the site. A limited number of the PCB detections were above applicable RSLs.

    - Aroclor 1254 was detected in 1997 at sample location SS-09 (8.3 mg/kg) next to Building 405. Aroclor 1254 was detected in 2002 at sample location BLASS01 (3.2 mg/kg) next to Building 405 and previous sample SS-09. These concentrations were above the industrial RSL for Aroclor-1254 of 0.74 mg/kg. Aroclor 1254 was not detected above the residential RSL in two surface soil samples (BLASB01 and BLASS02) and one subsurface soil sample (BLASB01

(2-4) collected in 2002 in the vicinity of the previous detects. Aroclor 1254 was also not detected above the residential RSL in one surface soil sample (BLA-SS001) and two subsurface soil samples (BLA-SB001 (1-2) and BLA-SB001 (2-3) collected in 2008 in the vicinity of the previous detects. Therefore, the detections at BLASS01 and SS-09 north of Building 405 appear to be isolated.

- o No other surface soil or subsurface soil samples collected adjacent to BLA buildings contained PCBs at concentrations above applicable residential RSLs.

- Several SVOC/PAH compounds were detected at concentrations above applicable RSLs in five soil samples collected near the center of the BLA site and sporadically in surface soil samples collected around the perimeter of buildings containing conductive flooring. PAH compounds detected above RSLs included: benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene.

- Several inorganics were detected in soil samples collected around the BLA buildings at concentrations above applicable RSLs. In most cases the concentrations above the applicable RSLs were detected in surface soil samples collected immediately adjacent to buildings with conductive flooring material. Inorganics concentrations typically decreased considerably with depth and distance from the buildings. Inorganics concentrations also varied along the length of the buildings; likely due to the presence of preferential flow paths that would have carried the degraded flooring materials from the buildings. Inorganics that were detected above RSLs included:

  - o **Aluminum** – Aluminum was detected at concentrations above the residential RSL and slightly above the established background level (40,041 mg/kg) in three subsurface soil samples [407712 (2-3 ft bgs), BLASB01 (2-4 ft bgs), and BLASB02 (2-4 ft bgs]. Aluminum was not detected at concentrations above background in any surface soil or other subsurface soil samples at the BLA.

  - o **Arsenic –** Arsenic was detected above the background level and industrial RSL in two surface soil samples (BLA-SS013 and BLA-SS014). The maximum detected arsenic concentration (47.2 mg/kg) occurred in sample BLA-SS014 collected 1-ft from Building 404 in

2008. The other sample (BLA-SS013) contained arsenic at a concentration only slightly higher than background.

- **Barium** - Barium was detected above the residential RSL and established background level in ten surface soil samples. Three of the samples with detections above the residential RSL were collected adjacent to Building 404 (BLASB03, BLA-SS014, and BLA-SS019). Seven of the samples with detections above the residential RSL were collected adjacent to Building 405 (SS-09, BLASS03, BLA-SS007, BLA-SS008, BLA-SS009, BLA-SS011, and BLA-SS012). The maximum detected barium concentration of 11,100 mg/kg at sample location BLA- SS008 was also collected 1 ft from Building 405. The other samples that had barium concentrations above residential RSLs were collected with 1-10 ft of buildings with conductive flooring. Barium was not detected above RSLs in any subsurface soil samples.

- **Cadmium** – Cadmium was detected above background levels and the residential RSL in ten surface soil samples collected within 10-ft of BLA buildings. Three of the samples with detections above the residential RSL were collected adjacent to Building 404 (BLASB03, BLA-SS014, and BLA-SS016). Five of the samples with detections above the residential RSL were collected adjacent to Building 405 (BLASS03, BLA-SS007, BLA-SS008, BLA-SS011, and BLA-SS012). Two of the samples with detections above the residential RSL were collected adjacent to Building 406 (BLASS08 and BLA-SS013). Cadmium was not detected above the industrial RSL in any samples.

- **Cobalt** –Cobalt was detected above both the established background concentration and the industrial RSL in one surface soil sample near Building 406 (BLA-SS11) and one subsurface soil sample next to Building 407 [407712 (2-3 ft bgs)]. Cobalt was not detected above background levels in any other soil samples at the site.

- **Copper** – Copper, which is thought to have been a major component of the conductive flooring material, was the inorganic most frequently detected at concentrations above applicable RSLs.

  - Copper concentrations were detected above the industrial RSL of 4,100 mg/kg in six surface soil samples (SS-09, BLA-

SS001, BLA-SS008, BLA-SS013, BLA-SS014, and BLA-SS017) at the BLA. The samples with concentrations above industrial RSLs were all collected within 1-5 ft of buildings with conductive flooring material.

§ Copper was detected above both the established background concentration and between the residential RSL (310 mg/kg) and the industrial RSL in 15 surface soil samples surrounding BLA buildings with conductive flooring.

§ The highest detected concentration of copper (72,000 mg/kg) occurred at sample location BLA-SS013, next to Building 406 during the 2008 sampling event. Each of the seven BLA buildings containing conductive flooring had at least one adjacent soil sample with copper concentrations above RSLs and background concentrations.

o **Lead** – Lead is also believed to have been a major component of the conductive flooring material, and was the inorganic second most frequently detected at concentrations above applicable RSLs.

§ Lead was detected at concentrations above the residential RSL (400 mg/kg) in 16 surface soil samples collected at the BLA. Of these detections, 14 surface soil samples were also above the industrial RSL of 800 mg/kg. No subsurface soil samples contained lead at concentrations above the residential RSL.

§ All of the surface soil samples with concentrations above residential RSLs were collected within 10 ft of Buildings 404, 405, 406, and 407. The results of the XRF sampling also indicated that lead concentrations above RSLs were confined to surface soils within 10 ft of BLA Buildings 404, 405, 406, and 407.

o **Iron** – Iron was detected above the residential RSL and background levels in two surface soil samples (BLA-SS002 and BLA-SS012) and one subsurface soil sample BLASB01. The maximum detected

Bag Loading Area

concentration was 61,500 mg/kg at sample location BLA-SS012, which was collected 5 ft from Building 405.

- **Manganese**– Manganese was detected at a concentration above the industrial RSL in one surface soil sample (BLASS11) collected approximately 20 ft from Building 405. Manganese was not detected above established background concentrations in any subsurface or in other surface soil samples at the BLA. The concentration of manganese in sample BLASS11 appears to be an anomaly, unrelated to site activities, and therefore manganese is not considered a COC at the BLA.

- **Mercury** – Mercury was detected in three surface soil samples (BLASS03, BLA-SS009, and BLA-SS016) at concentrations above industrial RSLs. Two of the surface soil samples were collected adjacent to Building 405 and one was collected adjacent to Building 404.

- **Zinc** – Zinc was detected above both the established background level of 202 mg/kg and the residential RSL in 8 surface soil samples at the BLA. Zinc was not detected above the industrial RSL in any surface or subsurface soil samples. The samples with zinc concentrations above residential RSLs typically occurred with 1-5 ft of Buildings 404, 405, and 406.

During ARCADIS' 2008 site investigation, asbestos was detected in all of the surface soil samples collected within 1-10 ft of the BLA buildings where conductive flooring material has washed off of the building pads (Buildings 404, 405, 406, 407, 411, 412, and 413). However, during the 2009 investigation it was demonstrated that while chrysotile asbestos fibers are present in the surface soil around these buildings, the concentrations are generally very low (i.e., 0.1% by weight or less) at distances of 1-ft and greater from the building pad. Only one sample during the 2009 investigation contained asbestos at a concentration above 1%; that was BLA-SS026A (9.4% asbestos by weight), which was collected 1 ft from Building 406. The sample collected 5 ft from Building 406 (BLA-SS026B) had a reported concentration of <0.1%, which demonstrates that the asbestos fibers are not migrating at high concentrations from the edge of the building. Visual observation of the degraded flooring material that has washed off the building pads indicates that it is generally confined to the soil immediately adjacent to the buildings.

While asbestos in soil is not inherently hazardous, the activity based sampling event conducted at the BLA demonstrated that intensive soil disturbance activities in areas located immediately adjacent to the buildings has the potential to result in measureable concentrations of asbestos in air. Asbestos can pose a potential hazard to human receptors in an airborne state. TEM analysis conducted on personal air monitoring pump and perimeter air monitoring pump filter samples associated with activity based sampling in a grid located within 0-10 ft of BLA Building 404 indicated asbestos concentrations in air of 0.0218 s/cc and 0.0899 s/cc, respectively. Likewise, activity based sampling conducted within 0-10 ft of Building 411 resulted in airborne asbestos concentrations of 0.0783 s/cc and 0.0345 s/cc in the personal air monitoring pump and perimeter air monitoring pump samples, respectively. Activity based sampling conducted in grids located 10-20 ft from Buildings 404 and 411 did not generate airborne asbestos.

6.5.1.2 Former Transformer Area Assessment

The PCB Aroclor 1254 was detected in surface soils near two former transformer locations at the BLA. One sample collected from a former transformer location east of Building 416 (BLATR01) contained Aroclor 1254 at a concentration above the industrial RSL. Two samples (SS09 and BLASS01) collected near a former transformer at the northwest corner of Building 405 also contained Aroclor 1254 at concentrations above the industrial RSL. Additional samples collected in the vicinity of these two locations did not contain any PCBs at concentrations above applicable screening levels indicating that the detections of Aroclor 1254 were isolated. PCBs were not detected at other former transformer locations at the site and PCBs have not been detected in sediments or surface water samples at the BLA.

6.5.1.3 Summary of Soil Investigation

In summary, the environmental investigations at the BLA have confirmed that soils surrounding four of the buildings (Buildings 404, 405, 406, and 407) have been affected by asbestos and inorganics from the deteriorating conductive flooring material. Inorganics, primarily copper and lead, and to a lesser extent arsenic, barium, cadmium, mercury and zinc have been detected at concentrations above applicable RSLs. The elevated metals and asbestos concentrations are typically confined to soils in the immediate vicinity of the buildings (i.e., less than 5-ft distance from building footprint) with the exception of one or two discrete areas around each of four BLA buildings (Buildings 404, 405, 406, and 407), where the elevated metals concentrations extend from 10 to 15-ft from the buildings. Subsurface sampling has confirmed that the elevated concentrations affected by site activities are confined to surface soil, as no samples deeper than 2-ft bgs contained target inorganics at concentrations above background levels and residential RSLs. Aluminum and iron were detected in subsurface samples at concentrations above residential RSLs, but these inorganics do not appear related to site activities, as they were generally not detected at elevated concentrations in surface soils surrounding BLA buildings.

The PCB compounds that were detected above applicable RSLs in samples collected adjacent to BLA buildings and transformers have been delineated and are isolated to a small area north of Building 405.

PAHs were detected above applicable soil RSLs in surface soil samples collected in the center of the BLA and sporadically around the BLA buildings. PAHs do not appear to be more concentrated in areas closer to buildings and therefore are likely due to the presence of asphalt roads and other building materials through the BLA rather than related to conductive flooring or other site activities.

6.5.2 Surface Water

There is one small unnamed stream to the north of the BLA. Two surface water samples were collected from the stream in 2002. The pesticide dieldrin was detected above the tap water screening value (0.0042 µg/kg) in one of the two samples (BLASW05) at a concentration of 0.0058 µg/kg. No other constituents were detected in either sample at concentrations above tap water screening values. A site map depicting the constituents detected in surface water samples during the BLA investigation is presented as Figure 6-10.

Two water samples were collected from ponded water within an elevator shaft and a concrete subsurface vault at Building 405 during the 2008 investigation. Arsenic was detected at concentrations above the tap water screening value in both samples. No other constituents were detected above respective tap water screening values.

6.5.3 Sediment

There is one small unnamed stream to the north of the BLA. No constituents were detected above soil RSLs and established background concentrations (inorganics only) in sediment samples collected from the stream. There are also several drainage ditches located within the boundaries, and on the perimeter, of the BLA. During the course of environmental investigation at the BLA, samples have been collected from the drainage pathways to evaluate the potential for runoff from the buildings and other areas of the site to have transported constituents into the ditches. The samples collected from the drainage ditches have been called sediment samples due to the loose nature of some of the material, but would be more accurately classified as surface soil. The drainage ditches were all dry at the time of sampling. No constituents were detected at concentrations above applicable soil RSLs and established background concentrations (inorganics only) in any of the sediment samples collected from drainage ditches at the BLA. A site map depicting the constituents detected in sediment samples during the BLA investigation is presented as Figure 6-10.

One sample was also collected of solid material that had accumulated at the bottom of the elevator shaft discussed above. Copper was detected at a concentration above both the established background concentration for soil and the residential soil RSL. No other inorganics were detected above both of these criteria. Three PAHs (Benzo(a)pyrene, Benzo(b)fluoranthene, and Dibenzo(a,h)anthracene) were detected at concentrations above respective industrial soil RSLs and two PAHs (Benzo(a)anthracene and Indeno(1,2,3-cd)pyrene) were detected at concentrations above residential soil RSLs.

6.5.4 Conductive Flooring and Building Materials

Conductive flooring material is present on seven of the ten building pads at the BLA. Results of the conductive flooring survey indicate that there is approximately 19,000 ft^2 of conductive flooring present on building pads at the BLA. The condition of the flooring during the 2008 investigation ranged from mostly intact to highly deteriorated. Based on the flooring characterization sampling events, the flooring is known to contain aluminum, barium, cadmium, chromium, copper, iron, lead, and zinc; as well as several other inorganics that have been identified in soils at the BLA. The flooring material is also known to contain asbestos, which could pose a potential hazard to human receptors in a degraded, friable state.

While very little paint remains on the concrete walls of the BLA buildings, one paint chip sample collected in 2005 and analyzed for lead indicated that the paint does contain lead. However, the reported lead concentration (306 mg/kg) was below 0.5% by weight (i.e., 5,000 mg/kg) which is the minimum concentration that the federal government uses to define lead based paint in residences (40 CFR 745.223).

6.6 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. Risk assessment datasets for soil, sediment, and surface water for the BLA were prepared then summarized and statistically analyzed per methods described in Appendix A. Risk assessment dataset summaries highlighting the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPC are presented in Tables 6-15 through 6-19.

6.7 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with constituents detected in soil, sediment, and surface water samples collected at the BLA. The general risk assessment approach follows the Radford Army Ammunition Plant Final Master Work Plan (URS 2003). The approach for evaluating the risks associated with asbestos is somewhat different than the other constituents at the site. The approach for evaluating asbestos is presented in detail in Section 4.4.5 of Appendix A.

6.7.1 Selection of Constituents of Potential Concern

This section discusses the selection of COPCs for each medium.

6.7.1.1 Surface Soil

Surface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 6-20 presents the selection of surface soil COPCs for the HHRA. The following twenty-three constituents were identified as COPCs in surface soil:

- **VOCs:** 3-octanone and d-limonene;
- **SVOCs/PAHs:** carbazole, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene;
- **Explosives:** pentaerythritol tetranitrate;

- **PCBs:** Aroclor 1254; and

- **Inorganics:** antimony, arsenic, barium, cadmium, cobalt, copper, iron, lead, manganese, mercury and zinc.

In addition to the constituents listed above, asbestos has been identified as a COPC for surface soil at the BLA. Soil sampling conducted at the site has confirmed the presence of asbestos in soil immediately adjacent to site buildings where conductive flooring has washed off the building pads. While asbestos fibers in soil are not inherently hazardous, activity based sampling has indicated that intensive soil disturbance activities in the areas located immediately adjacent to the buildings, where soil asbestos concentrations are highest, have the potential to generate measureable concentrations of asbestos in air.

6.7.1.2 Combined Surface and Subsurface Soil

Combined surface and subsurface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 6-21 presents the selection of combined surface and subsurface soil COPCs for the HHRA. Twenty-four constituents were identified as COPCs in combined surface and subsurface soil, including:

- **VOCs:** 3-octanone and d-limonene;

- **SVOCs:** carbazole, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene;

- **Explosives:** pentaerythritol tetranitrate;

- **PCBs:** Aroclor 1254; and

- **Inorganics:** aluminum, antimony, arsenic, barium, cadmium, cobalt, copper, iron, lead, manganese, mercury and zinc.

6.7.1.3 Sediment

Sediment COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 6-22 presents the selection of sediment COPCs for the

HHRA. As summarized in Table 6-22, five constituents were identified as COPCs in sediment:

- **Inorganics:** aluminum, arsenic, cobalt, iron, and manganese.

6.7.1.4 Surface Water

Surface water COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for tap water. Table 6-23 presents the selection of surface water COPCs for the HHRA. As summarized in Table 6-23, six constituents were identified as COPCs in surface water:

- **Pesticides:** dieldrin; and

- **Inorganics:** arsenic, copper, lead, manganese, and mercury.

6.7.2 Human Health Risk Characterization

Although not currently occupied, under current land use conditions, site workers were identified as a potential receptor due to the industrial use of the BLA and surrounding area. Assuming hypothetical redevelopment of the area for residential land use, construction workers, adult and child residents were identified as potential receptors.

Exposure via direct contact to COPCs in soil, sediment, and surface water were evaluated. Exposure via inhalation of indoor air to VOCs identified as COPCs in soil at the BLA were also evaluated. Two VOCs, 3-octanone and d-limonene, were identified as COPCs in soil at the BLA. Those two COPCs do not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area. In addition, potential risks associated with inhalation of asbestos becoming airborne from soil were estimated. These are summarized in Section 6.7.3. The uncertainty associated with the lack of toxicity values is presented In Appendix A. The EPCs for the BLA are presented in Table 6-24.

The excess lifetime cancer risks and non-cancer hazards and the blood lead level model estimates for each potentially exposed receptor included in the risk assessment for the BLA are presented in Appendix A. These results are presented in the tables below and are discussed by receptor in following subsections.

Bag Loading Area

Summary of Calculated ELCRs and HIs for Receptor Exposure Scenarios.

RECEPTOR/ EXPOSURE MEDIUM - SCENARIO	ELCR	HI
Site Worker		
Surface Soil - Direct Contact	1E-04	0.7
Sediment – Wading	4E-07	0.007
Surface Water – Wading	2E-06	0.05
TOTAL SITE RISKS (Site Worker):	**1E-04**	**0.8**
Hypothetical Future Construction Worker		
Combined Surface and Subsurface Soil - Direct Contact	7E-06	3
TOTAL SITE RISKS (Construction Worker):	**7E-06**	**3**
Hypothetical Future Adult Resident		
Combined Surface and Subsurface Soil - Direct Contact	-	1
Sediment – Wading	-	0.01
Surface Water – Wading	-	0.01
TOTAL SITE RISKS (Adult Resident):	**-**	**1**
Hypothetical Future Child Resident		
Combined Surface and Subsurface Soil - Direct Contact	-	12
Sediment – Wading	-	0.09
Surface Water – Wading	-	0.04
TOTAL SITE RISKS (Child Resident):	-	**12**
Hypothetical Future Resident (Adult and Child)		
Combined Surface and Subsurface Soil - Direct Contact	1E-03	-
Sediment – Wading	1E-06	-
Surface Water – Wading	1E-06	-
TOTAL SITE RISKS (Child Resident):	**1E-03**	**-**

Summary of Estimated Blood Lead Levels for Receptor Exposure Scenarios.

RECEPTOR	Estimated Blood Lead Level (µg/dL)		
	Adult	**Child**	**Fetus**
	50th percentile	**Range**	**95th percentile**
Site Worker	4.9	–	17
Hypothetical Future Construction Worker	5.2	–	18
Hypothetical Future Child Resident	–	11 – 18	–
Hypothetical Future Adult Resident	6.5	–	23

*See Appendix A for individual tables.

Bag Loading Area

Levels of asbestos measured in air during the activity based sampling were greater than the AALs developed for the site worker and resident. Thus, asbestos in soil also poses an unacceptable risk under both industrial and residential land uses.

6.7.2.1 Site Worker

A current or future site worker could be present at the BLA area, and could be exposed to surface soil, sediment, and surface water. The ELCR and non-cancer hazard index for site worker exposure to each medium are presented in Appendix A, and are summarized in Table 6-25. As presented in the table above, the ELCRs for surface soil, sediment, and surface water are all within or equal to the high end of the USEPA target risk range, and the HIs for each medium are all below the benchmark value of 1.

The total cumulative ELCR for site workers exposed to surface soil, sediment, and surface water at the BLA is 1×10^{-4}, which is equal to the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. This is due to the presence of benzo(a)pyrene in surface soil. The total cumulative HI for site workers is 0.8, which is less than the benchmark of 1.

The 50^{th} percentile blood lead level estimates for the site worker receptor was at 4.9 micrograms per deciliter (µg/dL), below the benchmark of 10 µg/dL; however the 95^{th} percentile fetal blood lead level was 17 µg/dL which exceeds the benchmark.

6.7.2.2 Hypothetical Future Construction Worker

A hypothetical future construction worker could be present at the BLA area, and could be exposed to combined surface and subsurface soil. The ELCR and non-cancer hazard index for hypothetical future construction worker exposure to soil are presented in Appendix A, and are summarized in Table 6-25. As presented in the table above, the ELCR for combined surface and subsurface soil is within the USEPA target risk range, and the HI is above the benchmark value of 1.

The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the BLA is 7×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction worker is 3, which is above the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were above the benchmark of 1 in the gastrointestinal tract due to the presence of copper.

The 50th percentile blood lead level estimates for the construction worker receptor was at 5.2 µg/dL below the target level of 10 µg/dL; however the 95th percentile fetal blood lead level was calculated to be 18 µg/dL which exceeds the benchmark.

6.7.2.3 Hypothetical Future Residents

A hypothetical future resident could be present at the BLA area, and could be exposed to surface soil, sediment, or surface water. The ELCR and non-cancer hazard index for hypothetical future adult or child resident exposure to each medium are presented in Appendix A, and are summarized in Table 6-25.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water at the BLA is 1×10^{-3}, which is greater than the USEPA target risk range of 1×10^{-6} to 1×10^{-4}, due to the presence of benzo(a)pyrene. The ELCRs for hypothetical future residential exposure to sediment and surface water are both equal to the low end of the USEPA target risk range; however, the ELCR for combined surface and subsurface soil was above the USEPA risk range. The HIs for each medium are all below the benchmark value of 1, with the exception of the child resident exposure to combined surface and subsurface soil.

The total cumulative HI for hypothetical future adult residents is equal to the benchmark of 1. The total cumulative HI for hypothetical future child residents is 12, which is greater than the benchmark of 1. When the HI is segregated into target site and critical effects, hazards exceed the benchmark of 1 for the GI tract, due to copper; the eyes, nails hair and skin, due to cobalt and Aroclor 1254; and the immune system, due to Aroclor 1254.

The 50th percentile blood lead level estimates for the hypothetical adult resident receptor was 6.5 µg/dL which is well below the benchmark of 10 µg/dL; however the 95th percentile fetal blood lead level was predicted to be 23 µg/dL, which is greater than the benchmark. The range of blood lead level estimates for the child receptor was 11 µg/dL to 18 µg/dL looking at annual predicted blood lead levels which is greater than the benchmark of 10 µg/dL. The predicted exposure of a child over a seven year period resulted in a geometric mean blood lead concentration of 14.9 µg/dL, also above the 10 µg/dL benchmark and a prediction of 80 percent of the population having blood lead concentrations above the 10 µg/dL benchmark.

6.7.3 Asbestos Evaluation

As discussed in Appendix A, the risks and hazards associated with asbestos in soil cannot be evaluated utilizing traditional risk assessment techniques. This is because the measurement of asbestos in soils may not be a good indicator of potential for exposure due to the fact that the main route of asbestos toxicity is through inhalation of fibers. Thus, the important metric in defining potential risk is the measurement of asbestos fibers in air within a breathable zone. Based on this information, USEPA recommends that the results of activity-based air sampling be utilized to determine whether disturbance of soils in areas known to contain asbestos can result in the mobilization of asbestos into air at potential hazardous levels where it may be inhaled by the individuals engaged in activities there.

To evaluate the results of the activity based sampling conducted at the BLA in 2009, risk based Air Action Level (AALs) for relevant, site-specific exposure scenarios have been developed in accordance with the methods outlined in the USEPA's Framework for Investigating Asbestos-Contaminated Superfund Sites (2008f). AALs were calculated for all of the exposure scenarios identified at the BLA including the current and future site worker, the hypothetical future construction worker, the hypothetical future adult resident, and the hypothetical future child resident. AALs were also calculated for each potential receptor group at the 1E-06 and 1E-04 risk levels, representing the lower and upper ends of USEPA's acceptable risk range. The calculation of the AALs is presented in detail within Section 4.4.5 of Appendix A. The calculated AALs are presented in the following table.

	Calculated AAL (s/cc) at Indicated Target Risk Level	
Receptor Group	**Target Risk = 1E-06**	**Target Risk = 1E-04**
Current/Future Site Worker	0.00007	0.007
Hypothetical Future Construction Worker	0.002	0.2
Hypothetical Future Child Resident	0.00002	0.002
Hypothetical Future Adult Resident	0.00001	0.001

The total asbestos concentration measured in air at Building 404 was non-detect in samples taken from the activity based sampling grid located 10-20 feet from the building edge (sample IDs: BLA404-AA2 and BLA404-AP2). However, asbestos was detected in air samples taken from the activity based sampling grid located immediately adjacent to the building (0-10 feet from building edge) (sample IDs: BLA404-AA1 and BLA404-AP1). At BLA404-AA1, the total asbestos structures (specifically chrysotile) measured by Total TEM were 0.022 s/cc; total asbestos structures (i.e., chrysotile) measured at BLA404-AP1 were 0.090 s/cc. The average of all airborne asbestos samples at Building 404, including the two samples where it was non-detect, was 0.028 s/cc. All of these exceed the AAL of 0.007 s/cc (based on a 1E-04 risk level) calculated for the current and future site worker, as well as the AALs of 0.001 and 0.002 s/cc calculated for the hypothetical future child and adult residents, respectively. None of these exceed the AAL of 0.2 calculated for the hypothetical future construction worker.

The total asbestos concentration measured in air during the activity based sampling at Building 411 was similar to Building 404. The total asbestos concentrations measured in air during the activity based sampling conducted in the grid located nearest the building (sample IDs: BLA411-AA1 and BLA411-AP1) were 0.078 and 0.034 s/cc, respectively. The activity based air samples collected from the grid located 10-20 ft from Building 411 (sample IDs BLA411-AA2 and BLA411-AP2) were non-detect for asbestos. For all four samples at Building 411, the average concentration is 0.028 s/cc. The samples from the 0-10 ft grid and the building average exceed the calculated AALs for the current/future site worker and the hypothetical future residents, but do not exceed the calculated AAL for the hypothetical future construction worker.

This comparison indicates that the presence of asbestos in the soils closest to Buildings 404 and 411, and other buildings with conductive flooring at the BLA may result in unacceptable air concentrations if those soils are subject to intensive disturbance. These unacceptable risks would be expected under the current/future industrial scenario and hypothetical future residential exposure scenarios.

6.7.4 Human Health Risk Summary

Table 6-25 summarizes the calculated cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the BLA. As shown in the table above, the total ELCR values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below or within the benchmark range of 10^{-6} to 10^{-4} for cancer risk, with the exception of hypothetical future resident exposure to combined surface and subsurface soil. The risk driver in this exposure scenario is benzo(a)pyrene.

The total HI values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below the benchmark of 1 for non-cancer hazard, with the exception of hypothetical future construction worker and hypothetical future child resident exposure to combined surface and subsurface soil. When the HIs are segregated into target site and critical effects, hazards were only greater than the benchmark of 1 in the gastrointestinal (GI) tract for the hypothetical future construction worker, due to copper. For the hypothetical future child resident exposure to surface soil, hazards exceed the benchmark of 1 for the GI tract, due to copper; the eyes, nails hair and skin, due to cobalt and Aroclor 1254; and the immune system, due to Aroclor 1254.

The results of the risk assessment indicate that under industrial exposure scenarios, exposure to lead may pose an unacceptable risk. The predicted blood lead levels for the worker were below the benchmark, but the fetal blood lead levels were above the benchmark. In addition, predicted blood lead levels for a future hypothetical child resident were also greater than the benchmark.

As discussed in Section 6.5, removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and wash onto the surrounding soils. Activity based sampling conducted at the BLA has demonstrated that intensive disturbance of the soils located immediately adjacent to the buildings where the flooring has washed off the building pads has the potential to generate airborne asbestos concentrations that may present an unacceptable risk to human receptors under current and hypothetical future industrial and/or residential land use scenarios. Soil sampling at the BLA has indicated that the elevated concentrations of asbestos in soil that have the potential to generate the airborne asbestos concentrations are primarily located immediately adjacent to the site buildings, which is the same general area where the inorganic risk drivers are located.

While not evaluated in the risk assessment any residual lead based paint on the concrete walls at the BLA or other possible asbestos containing building materials (i.e., pipe insulation, joint compounds, mastic, etc.) could also present a risk for current and future site workers, construction workers, or residents.

6.8 Ecological Risk Assessment

The purpose of the ERA is to evaluate whether ecological receptors may be adversely impacted by exposure to site-related constituents detected in surface soil, sediment, and surface water at the BLA. This section summarizes the occurrence of constituents in each medium and identifies COPECs at the BLA for the ecological risk assessment; identifies the potential ecological exposure scenarios relevant to the BLA; and presents the estimated ecological risks associated with the identified COPECs and the relevant ecological exposure scenarios at the BLA. Methodologies for data summary and selection of COPECs, exposure assessment, and toxicity assessment for the ERA are presented in Appendix A.

6.8.1 Selection of Constituents of Potential Ecological Concern

This section discusses the selection of COPECs for each medium. Risks to ecological receptors are calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the hazard quotient (HQ), is a highly conservative surrogate for the assessment endpoints identified in Appendix A. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse ecological effects are unlikely (USEPA 1997c). HQs greater than 1 indicate that further evaluation is warranted. Therefore, the constituents with HQs greater than 1 or that are identified as bioaccumulative are carried forward as COPECs into the BERA. Maximum HQs greater than 1 for the BLA area are summarized in the subsections below.

6.8.1.1 Surface Soil

Surface soil COPECs were selected by comparing the analytical data with USEPA (2005b) EcoSSLs, USEPA (2003e) Region 5 ESLs, and ORNL values (Efroymson et al. 1997a,b) for surface soil. Table 6-27 presents the selection of surface soil COPECs for the ERA. As summarized in Table 6-27, 53 constituents were identified as COPECs in surface soil:

- **VOCs:** 3-octanone and d-limonene;

- **SVOCs:** 2,4-dinitrotoluene,2,6-dinitrotoluene, benzoic acid, carbazole, dibenzofuran, di-n-butylphthalate, and n-nitrosodiphenylamine;

Bag Loading Area

- **Explosives:** 2,4,6-trinitrotoluene, m-nitrotoluene, nitroglycerine, and pentaerythritol tetranitrate;

- **Pesticides:** 4,4'-DDD, 4,4'-DDE, Endosulfan, beta-BHC, alpha-chlordane, endrin, heptachlor epoxide, and methoxychlor;

- **PAHs:** acenaphthene, acenaphthylene, anthracene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, naphthalene, phenanthrene, and pyrene

- **PCB:** Aroclor 1254;

- **Inorganics:** antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, silver, and zinc.

6.8.1.2 Sediment

Sediment COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008c) Region 3 Sediment Screening Levels; ORNL values (Jones et al. 1997); and USEPA (2003e) Region 5 Ecological Screening Levels for sediment. Table 6-28 presents the selection of sediment COPECs for the ERA. As summarized in Table 6-28, thirty constituents were identified as COPECs in sediment:

- **VOCs:** acetone

- **Pesticides:** 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, beta-BHC, alpha-chlordane, and dieldrin

- **PAHs:** anthracene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, phenanthrene, and pyrene

- **Inorganics:** arsenic, barium, beryllium, chromium, copper, lead, nickel, thallium, vanadium and zinc.

6.8.1.3 Surface Water

Surface water COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Surface Water Screening Levels; ORNL values (Suter and Tsao 1996); USEPA (2003a) Region 5 Ecological Screening Levels; and USEPA (2008e) Ambient Water Quality Criteria for surface water. Table 6-29 presents the selection of surface water COPECs for the ERA. As summarized in Table 6-29, 18 constituents were identified as COPECs in surface water:

- **Pesticides**: dieldrin
- **PAHs:** benzo[a]anthracene, benzo[b]fluoranthene, chrysene, fluoranthene, phenanthrene, and pyrene

- **Inorganics:** aluminum, arsenic, barium, chromium, copper, iron, lead, manganese, mercury, selenium, and zinc.

6.8.2 Summary of Selected Constituents of Potential Ecological Concern

Fifty-three constituents were selected as COPECs in surface soil, thirty constituents were selected as COPECs in sediment, and eighteen constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was identified as bioaccumulative, or an HQ couldn't be calculated because an ESL was not available.

6.8.3 Refinement of Risk Calculations for Direct Contact COPECs

The list of COPECs identified in the BERA was reevaluated by calculating refined HQs. The refined HQs were calculated for the COPECs identified in the SLERA using refined EPCs. Constituents identified as COPECs in the BERA that were bioaccumulative were carried forward into food chain models. The results of the recalculation of the HQs for the BDDT are summarized in the subsections below.

6.8.3.1 Surface Soil

Fifty-three COPECs in surface soil were carried forward into the BERA. When refined EPCs were compared with the ESLs, 20 constituents [2,6-dinitrotoluene, di-n-butylphthalate, n-nitrosodiphenylamine, 4,4'-DDD, methoxychlor, benzo(a)anthracene, benzo(a)pyrene, chrysene, naphthalene, antimony, barium, cadmium, chromium, cobalt, copper, lead, mercury, selenium, and zinc] had a refined HQ greater than 1. In addition, ESLs were not available for 12 other constituents (3-octanone, d-limonene, benzoic acid, carbazole, dibenzofuran, 2,4,6-trinitrotoluene, m-nitrotoluene, nitroglycerine, pentaerythritol tetranitrate, Endosulfan, Aroclor 1254, and iron). The BERA results for surface soil COPECs at the BLA are presented in Table 6-30 and are discussed in Appendix A. The refined analysis indicated that adverse impacts are not expected to occur.

Thirty-two of the soil COPECs were identified as bioaccumulative and were also evaluated in the terrestrial food chain model.

6.8.3.2 Sediment

Thirty COPECs in sediment were carried forward into the BERA. When refined EPCs were compared with the ESLs, only one constituent (acetone) had a refined HQ greater than 1. In addition, ESLs were not available for four other constituents (barium, beryllium, thallium, and vanadium). However, six pesticides, thirteen PAHs, and five inorganics were evaluated in the aquatic food chain model. The BERA results for sediment COPECs at the BLA are presented in Table 6-31 and discussed in Appendix A.

6.8.3.3 Surface Water

Eighteen COPECs in surface water were carried forward into the BERA. All but chromium were identified as bioaccumulative and evaluated in the aquatic food chain model. When refined EPCs were compared with the ESLs, 10 constituents (fluoranthene, pyrene, aluminum, arsenic, barium, copper, iron, lead, manganese, and mercury) had a refined HQ greater than 1. The BERA results for surface water COPECs at the BLA are presented in Table 6-32 and are discussed in detail in Appendix A. Based on the results of the BERA indicated that adverse impacts to aquatic life are not expected to occur.

6.8.4 Refinement of Assessment and Measurement Endpoints for Bioaccumulative COPECs

Food chain modeling was conducted at the BLA in order to evaluate the potential ecological effects of the bioaccumulative COPEC in soil, sediment, and surface water on the receptors identified in Appendix A. COPECs identified in soil were evaluated in the terrestrial food chain, and COPECs identified in sediment and surface water were evaluated in the aquatic food chain. The results for both the maximum and refined scenarios of these models are presented in Appendix A, and the results of each of the refined scenarios are discussed in the subsections below.

6.8.4.1 Terrestrial Food chain Model

As summarized in Table 6-33, the refined scenario LOAEL and NOAEL HQs for most COPECs were below 1 for both the short-tailed shrew and the American robin. Based on the overall analysis of terrestrial food chain modeling HQs, as presented in Appendix A, and consideration of the limited spatial extent of affected soils, adverse effects are not expected for short-tailed shrews (and other insectivorous mammals) and American robins (and other insectivorous birds) populations exposed to bioaccumulative COPECs in soil at the BLA.

6.8.4.2 Aquatic Food chain Model

As summarized in Table 6-34, the refined scenario LOAEL and NOAEL HQs for both the mink and the great blue heron were less than or equal to 1 for all bioaccumulative COPECs identified in sediment and/or surface water. These results indicate that mink and herons (or other piscivorous mammals and birds) exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of aquatic food chain modeling HQs, adverse effects are not expected for mink (and other piscivorous mammals) and great blue herons (and other piscivorous birds) populations exposed to bioaccumulative COPECs in sediment and/or surface water at the BLA.

6.8.5 Ecological Risk Summary

Screening-level and baseline risk assessments were completed for the BLA. After the SLERA, 53 constituents were selected as COPECs in surface soil, 30 constituents were selected as COPECs in sediment, and 18 constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was bioaccumulative, or an HQ could not be calculated because an ESL was not available. After the BERA, 52 constituents in surface soil, 39 constituents in sediment, and 17 constituents in surface water were retained because the HQs were greater than 1, the chemical was bioaccumulative or an HQ could not be calculated because an ESL was not available. Food chain modeling was evaluated for all those constituents identified as bioaccumulative.

Tables 6-33 and 6-34 summarize the constituents in surface soil, sediment, and surface water carried through the BERA and evaluated in the terrestrial and/or aquatic food chain model. Although there are a few HQs that exceed 1, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents in surface soil, the potential for population-level effects is low (Appendix A, Figure 6-5). As shown in Table 6-34, all constituents evaluated in the aquatic food chain refined scenarios had LOAEL and NOAEL HQs less than or equal to 1. These results indicate that individual mink and herons (or other piscivorous mammals and birds) potentially exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of the ERA for the BLA, the results indicate that adverse effects are not expected for wildlife at the site.

6.9 BLA Summary and Conclusions

The BLA is a former powder bag loading facility that operated from 1941 through 1943. The facility included a total of ten buildings that were connected by elevated walkway platforms. Seven of the buildings (Buildings 404, 405, 406, 407, 411, 412, and 413), contained a conductive flooring material that covered the concrete slab floors (including the second story of Buildings 404 and 405). Samples of the conductive flooring material indicate that it contained asbestos and several different metals. All process equipment, wooden roofs, and wooden walls have been removed from the buildings, leaving only concrete slabs and walls in place. Removal of the building wall and roofs has exposed the conductive flooring to weather, causing it to degrade and begin to break away from the underlying concrete. In many cases, the flooring has degraded into a red powder-like material and washed onto the surrounding soils.

Environmental investigations conducted at the BLA between 1997 and 2008 focused on evaluating the effects that the deteriorating conductive flooring material and historical site operations have had on the soils surrounding the BLA buildings. Soil samples were also collected at former electrical transformer locations, near area walkways, and from area drainage ditches. Sediment and surface water samples were collected from the unnamed stream located to the north of the BLA to evaluate the potential for constituents to have migrated from the site. Water and sediment samples were also collected from an underground utility vault and former elevator shaft in Building 405. Laboratory analyte classes varied between the investigation activities but have included explosives, herbicides, pesticides, PAHs, PCBs, VOCs, SVOCs, TAL inorganics, asbestos, TCLP-inorganics, and lead-based paint analysis. An extensive soil sampling program was also conducted in 2008 that included screening 192 soil samples around BLA buildings for lead using XRF.

The primary constituents of concern identified during the investigation at the BLA are associated with the deteriorating conductive flooring in the existing structures. Inorganics, including arsenic, barium, cadmium, cobalt, copper, lead, and zinc have been detected in surface soil samples collected around the buildings. Lead and copper, which are believed to have been the primary components of the conductive flooring material, were the most frequently detected constituents at concentrations above applicable industrial and residential RSLs. The 2008 sampling activities confirmed that the inorganics concentrations above applicable RSLs and/or background levels are generally limited to surface soils immediately adjacent (i.e. within 1 to 5 ft) to buildings with conductive flooring material; although, the elevated concentrations extend up to 10 ft from buildings in a few isolated areas. Subsurface soil sampling activities at the BLA have not identified any of the inorganics associated with the flooring material at concentrations above the applicable RSLs. Samples collected from BLA drainage ditches have also indicated that the concentrations of inorganic constituents were within background levels. The subsurface soil and drainage ditch sampling results indicate that the mobility of these constituents is very limited. The only inorganics detected at concentrations above applicable RSLs and background inorganics concentrations in subsurface soil were aluminum (2 samples) and iron (1 sample).

PAHs, which are possibly associated with the flooring material and other building materials used at the BLA are also present in surface soils around the BLA buildings and former elevated walkway corridors. Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were detected in several surface soil samples at concentrations above industrial and residential RSLs. Concentrations of PAHs did not exceed residential RSLs in subsurface soil samples at the BLA or in drainage ditch samples.

Asbestos, another component of the conductive flooring and other BLA building materials, has been identified in surface soils surrounding the various BLA buildings.

The PCB Aroclor 1254 was detected in surface soils near two former transformer locations at the BLA. One sample collected from a former transformer location east of Building 416 (BLATR01) contained Aroclor 1254 at a concentration above the industrial RSL. Two samples (SS09 and BLASS01) collected near a former transformer at the northwest corner of Building 405 also contained Aroclor 1254 at concentrations above the industrial RSL. Additional samples collected in the vicinity of these two locations did not contain any PCBs at concentrations above applicable residential screening levels indicating that the detections of Aroclor 1254 were isolated. PCBs have not been detected in sediments or surface water samples at the BLA, further supporting the theory that constituents are not migrating from the BLA.

Sediment and surface water samples were collected from two locations in the unnamed stream that passes to the north of the BLA during the 2002 site investigation. While the data indicated that several pesticides, and PAHs were present at low concentrations in the sediment, no constituents were detected at concentrations above applicable RSLs. The pesticide dieldrin was detected in one surface water sample (BLASW05) from the unnamed creek north of the BLA, at a concentration above the tap water RSL; however, dieldrin was also detected in other surface water samples collected from the unnamed stream in 2002, upstream of the BLA; including a sample where the unnamed stream first enters the RFAAP-NRU (WBGSW14). No other constituents were detected in stream surface water at concentrations above applicable tap water RSLs.

Water samples collected from two utility vaults identified at the BLA (at Building 405) in 2008 contained arsenic at concentrations above the tap water RSL. No other constituents were identified in the vault water samples at concentrations above applicable RSLs.

For the purposes of the HHRA, surface soil, total soil, surface water and sediment were evaluated for both current and future land-use conditions. Under current land-use conditions, site worker exposures to surface soil, surface water, and sediment were evaluated. Under future conditions, the site worker exposures remained the same as the current exposures and construction or excavation worker, adult resident and child resident exposures to total soil, surface water, and sediment were evaluated.

The potential cumulative cancer risks for site workers and hypothetical construction workers under current and future land-use conditions at the BLA were within the generally acceptable ELCR target risk range of 1×10^{-6} to 1×10^{-4} for health protectiveness at Superfund sites (USEPA, 1990). The cumulative ELCRs for hypothetical future residents was greater than the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The risk driver under for the residential scenario is benzo(a)pyrene.

Bag Loading Area

The total HI values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below the benchmark of 1 for non-cancer hazard, with the exception of hypothetical future construction worker and hypothetical future child resident exposure to combined surface and subsurface soil. When the HIs are segregated into target site and critical effects, hazards were only greater than the benchmark of 1 in the gastrointestinal (GI) tract for the hypothetical future construction worker, due to copper. For the hypothetical future child resident exposure to surface soil, hazards exceed the benchmark of 1 for the GI tract, due to copper; the eyes, nails hair and skin, due to cobalt and Aroclor 1254; and the immune system, due to Aroclor 1254.

Lead was also a constituent of potential concern for each of the receptors considered in the BLA risk assessment. For the current industrial and future hypothetical residential land use scenarios, exposure to lead resulted in predicted blood lead levels greater than the benchmark.

Removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and wash onto the surrounding soils. Activity based sampling conducted at the BLA has demonstrated that intensive disturbance of the soils located immediately adjacent to the buildings where the flooring has washed off the building pads has the potential to generate airborne asbestos concentrations that may present an unacceptable risk to human receptors under current/future industrial exposure scenarios and hypothetical future residential land use scenarios. Activity based sampling has also indicated that airborne asbestos fibers are not generated at distance from the buildings where asbestos concentrations in soil are low. Soil sampling at the BLA has indicated that the elevated concentrations of asbestos in soil that have the potential to generate the airborne asbestos concentrations are primarily located immediately adjacent to the site buildings, which is the same general area where the inorganic risk drivers are located.

While not evaluated in the risk assessment any residual lead based paint on the concrete walls at the BLA or other possible asbestos containing building materials (i.e., pipe insulation, joint compounds, mastic, etc.) could also present a small risk to current and future receptors. However, it should be noted that the overall extent of these materials at the site is limited. It should also be noted that the one paint chip sample collected at the BLA during the RI activities contained lead at a concentration below the federal standard for lead based paint of 5,000 mg/kg.

Bag Loading Area

A SLERA and BERA were completed for the BLA, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial food chain models indicate that some of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, affects of these COPECs at the population-level are unlikely at the BLA. All constituents evaluated in the aquatic food chain refined scenarios had LOAEL and NOAEL HQs less than or equal to 1, indicating that individual mink and herons (or other piscivorous mammals and birds) potentially exposed to COPECs are not expected to experience adverse effects.

The environmental investigations completed at the BLA have successfully defined and delineated the extent of effects that historical operations and degrading flooring material have had on environmental media at the site. The investigations have confirmed that the effects are generally limited to surface soils located immediately adjacent to buildings with conductive flooring, former elevated walkways, and two former transformer locations. The results of the HHRA activities indicated that lead, copper, and asbestos would be the primary risk drivers under the industrial site worker and construction worker exposure scenarios. Under the hypothetical future residential land use scenario, benzo(a)pyrene, Aroclor 1254, cobalt, copper, lead and asbestos were also found to be potential risk drivers. The ERA activities indicated the potential for risk to individual ecological receptors (i.e., short-tailed shrew and the American robin) due to Hazard Quotients (HQs) greater than 1 for Aroclor 1254, cadmium, copper, lead, and zinc; although no adverse population-level effects would be expected due to the limited areal distribution of these constituents.

An FS is recommended for the BLA to assess potential remedial alternatives to mitigate the unacceptable risks and hazards associated with the site soils, conductive flooring material, and other building materials.

7. Igniter Assembly Area

7.1 Site Description and History

The IAA is located in the western portion of the RFAAP-NRU (Figure 1-2). Many of the buildings in this area were used for the assembly of igniter charges used for artillery, cannon, and mortar projectiles. To support the igniter assembly operations there were also several outparcel buildings that were used to store and prepare the black powder used in the igniters. There were also buildings used for the shipping and receiving of materials related to the IAA as well as offices, change houses, and break rooms. The main igniter assembly buildings (Buildings 8102-1 through 8102-8, and Buildings 502, 504, 522 and 522A), and many of the outparcel buildings that handled the igniter materials contained, conductive flooring material similar to the BLA buildings. This conductive flooring was used to prevent the buildup of static electrical charges which could have potentially ignited explosive materials during assembly operations. The buildings with conductive flooring at the IAA are depicted on Figure 7-1. This flooring material contains various heavy metals and asbestos and was exposed to the weather when the wooden roof and walls were removed from the buildings. As a result, the conductive flooring has degraded into a red powder-like substance very similar to what has been observed at the BLA. In many areas, the degraded conductive flooring material has washed off the concrete pads onto surrounding surface soils. The concrete walls of many buildings were also painted with lead-based paint. Deterioration of the paint may have provided a potential source of lead to the soils immediately surrounding the former building areas

7.2 Physical Setting

The areas surrounding the main assembly buildings and multiple outparcel buildings are generally flat and vegetated with tall grass, shrubs, and pine trees. Previously maintained grassy areas have been allowed to revert to more natural conditions. Raised concrete sidewalks connect the assembly buildings with various outbuildings; however, none of these sidewalks were constructed with conductive flooring. A change-house/canteen (Building 8101) has been removed to its foundation. Building 8101 also contains no conductive flooring material. An engineered drainage system around the IAA consists of a series of culverts to divert water under the sidewalks to ditches which eventually drain into the unnamed creek that provides drainage for much of the RFAAP-NRU. However, the length of the unlined ditches suggests that runoff from normal rain events would infiltrate prior to arriving at the creek.

Igniter Assembly Area

The soil at the site varies from fill material to native soil. Generally, native soil at the IAA belongs to the Groseclose Urban Land Complex soil grouping. Stratigraphic characterization indicates that the soil consists of yellowish-red to dark yellowish-brown to strong brown silt and silty clay. Below this lies a layer of mottled, moderately hard to soft clay with intermixed quartz gravel and weathered bedrock (saprolite). This material grades downward to a tight, saprolitic clay at approximately 25 ft bgs (IT 2001).

7.3 Conceptual Site Model

In accordance with the general CSM, presented in Section 3.5, potentially affected media at this site would include surface soil, subsurface soil, sediment, and surface water. Potential sources of adverse environmental effects at this site are historical manufacturing and storage operations, deteriorating conductive flooring material, deteriorating lead based paint, and PCB containing electrical transformers that were formerly located at the site. It is also possible that residual asbestos containing materials (i.e., pipe insulation, mastic, joint compounds, etc.) are present in some IAA buildings that could be released to the environment, or could have been released during historic building demolition activities.

Surface soils in the areas surrounding the buildings with conductive flooring material appear to have the greatest potential to exhibit effects from historical operations and from the conductive flooring material. Surface soils located next to the buildings show signs of staining as a result of deteriorated conductive flooring material washing off of the building pads. Due to the composition of the flooring material, soils next to the buildings are expected to exhibit elevated concentrations of metals and asbestos. Soil sampling at the IAA has indicated that the COPCs at the site are generally confined to surface soils. Therefore, contaminant infiltration into subsurface soils does not appear to be a major pathway.

The majority of the IAA area is relatively flat, therefore erosion and/or migration of surface soils is expected to be fairly minimal. However, during heavy rainfall events surface water run-off has the potential to carry COPCs and affected soils to area drainage ditches. These drainage ditches remain dry except during heavy rainfall events .

7.4 Environmental Investigations

The IAA was designated a Study Area for the RFAAP-NRU site due to the former manufacturing activities at the site and the presence of deteriorating conductive flooring in site buildings that are composed of various inorganics and asbestos. In addition to the conductive flooring there were PCB-containing transformers at the site. The presence of these materials at the site warranted investigations of site media including soil surrounding building and former transformer locations, as well as sediment from drainage ditches in the vicinity of these locations. Environmental investigations at the IAA have been on-going since 1997 and have included:

- 1997 – Preliminary Sampling by Dames and Moore, Inc.
- 1998 – Additional Characterization Sampling by Dames and Moore, Inc.
- 1997 and 1998 – Independent Sampling by Gannett Fleming
- 1998 – Remedial Investigation by ICF Kaiser Engineers, Inc. (ICF KE)
- 2002 – Conductive Flooring Assessment by USACE
- 2002 – Remedial Investigation by Shaw
- 2005 – Additional Characterization Sampling by Shaw
- 2008 – Remedial Investigation by ARCADIS
- 2009 – Supplemental Remedial Investigation by ARCADIS

The goals and findings of each of these investigations are summarized in the following sections. As discussed in Section 4.1, the constituent detections reported in these sections are compared to their medium specific screening criteria (i.e., RSLs), where applicable.

7.4.1 Preliminary Sampling, Dames and Moore, 1997

An initial December 1997 soil sampling effort was conducted by Dames and Moore, Inc., to provide an assessment of the lateral and vertical distribution of organic and inorganic constituents in soil around Buildings 8102-2, 8102-7, 502 and 504 at the IAA, resulting from historical operations and the weathering of the conductive flooring in the buildings. At each building, three soil boring locations were positioned in a line perpendicular to the building at distances of 1 ft, 3 ft, and 5 ft out from the sidewalk. Sample locations are shown on Figure 7-2. Three samples were collected from depths of 0 to 1, 1 to 2, and 2 to 3 ft bgs at the location 1 ft away from the sidewalk. For the sampling locations 3 ft and 5 ft away from the sidewalk, samples were collected at depths of 0 to 1 and 1 to 2 ft bgs. In total 15 surface soil samples and 20 subsurface soil samples were collected:

- 15 surface soil samples [50240 (0-1) through 81027260 (0-1)]
- 20 subsurface soil samples [50240 (1-2) through 8102727 (2-3)]

The surface and subsurface soil samples were analyzed as follows:

- Four surface and seven subsurface soil samples for SVOC analysis
- Seven surface and 11 subsurface soil samples for PCB analysis
- One surface and three subsurface soil samples for pesticides
- 15 surface and 20 subsurface soil samples for TAL metals;

The laboratory analytical results for the soil samples are summarized in Table 7-1 and the sample locations are depicted in Figure 7-2. The results indicated the following.

SVOCs. A total of seven different SVOC compounds were detected in soil samples during this phase of investigation (see Table 7-1). Two SVOCs, were detected at concentrations above industrial RSLs including:

- 2,4-Dinitrotoluene in sample 504360 (1-2); and
- Bis(2-ethylhexyl)phthalate in samples 504312 (0-1) and 504360 (1-2)

Three SVOCs were also detected at concentrations between the residential and industrial RSLs, including:

- 2,4-Dinitrotoluene in sample 504360 (0-1);
- bis(2-Ethylhexyl)phthalate in samples 504312 (2-3), 504336 (0-1), and 504360 (0-1); and
- Chrysene in sample 504360 (1-2).

No other SVOCs were detected at concentrations above residential RSLs.

PCBs. Aroclor 1254 was the only PCB detected in soil samples collected from the IAA (See Table 7-1). Aroclor 1254 was detected above the industrial soil RSL in two soil samples [504312 (0-1) and 504360 (1-2)] and at concentrations between the residential and industrial RSL in three samples [50240 (0-1), 504336 (0-1), and 504360 (0-1)].

Pesticides. Four pesticides (4,4'-DDT, Endosulfan II, endrin, and methyoxychlor) were detected in soil samples collected at Building 8102-7 (see Table 7-1). The detected concentrations were below residential RSLs. Pesticides were not detected in samples collected at the other buildings.

Inorganics. Several inorganics were detected in all of the soil samples collected from the IAA (see Table 7-1). Three inorganics were detected at concentrations above industrial RSLs and established background concentrations in at least one soil sample, Including:

- Chromium in surface soil sample 504360 (1-2 ft bgs)
- Lead in surface and subsurface soil samples 504312 (0-1 ft bgs), 504336 (0-1 ft bgs), 504336 (1-2 ft bgs), 504360 (0-1 ft bgs), and 504360 (1-2 ft bgs)
- Mercury in surface soil sample 503460 (0-1 ft bgs)

Four inorganics were also detected at concentrations between the residential and industrial RSLs and above established background concentrations in at least one soil sample, including:

- Aluminum in sample 81027160 (1-2 ft bgs)
- Copper in samples 504312 (0-1 ft bgs), 504336 (0-1 ft bgs), 504360 (0-1 ft bgs), and 504360 (1-2 ft bgs)
- Chromium in surface soil samples 504312(0-1 ft bgs), 504336(0-1 ft bgs), and 504360 (0-1 ft bgs).
- Lead in surface soil sample 8102727 (0-1 ft bgs)
- Iron in samples 504312 (0-1 ft bgs) and 504360 (1-2 ft bgs),
- Zinc in sample 504360 (1-2 ft bgs)

While several other naturally occurring inorganics were detected in the soil samples, none were detected at concentrations above both residential RSLs and established background concentrations.

7.4.2 Additional Characterization Sampling, Dames and Moore, 1998

Additional characterization sampling in February 1998 was conducted by Dames and Moore, Inc. to enhance delineation of organic and inorganic constituents in soil around Building 8102-7 at the IAA. Three borings were advanced in locations of previous borings (81027112, 81027136, and 81027160) at Building 8102-7 from the 1997 investigation. The borings were advanced at locations that previously had only been analyzed for TAL metals. The following samples were collected during this investigation:

- Three surface soil samples were collected for SVOCs, PCB, and pesticides analyses.
- Four subsurface soil samples were collected for SVOCs, PCBs, and pesticides analyses.

The laboratory analytical results for the soil samples are summarized in Table 7-2 and the sample locations are depicted in Figure 7-2. The results indicated the following.

SVOCs. Only one SVOC [bis(2-ethylhexyl)phthalate] was detected during the February 1998 investigation (see Table 7-2). The detected concentration was below the residential RSL.

PCBs. No PCBs were detected in any of the surface or subsurface soil samples.

Pesticides. A total of two pesticides (4,4'-DDT and endrin) were detected during the February 1998 investigation (see Table 7-2). 4,4'-DDT was detected at a concentration above the residential RSL but below the industrial soil RSL in one surface soil sample (81027112 (0-1).

7.4.3 Independent Sampling, Gannett Fleming, 1997 & 1998

The objective of the independent sampling was to characterize surface soil at areas in the IAA that were not investigated previously. Initial investigation activities included the collection of two surface soil samples from the vicinity of IAA Buildings 8102-8 and 8102-5 in 1997 and five more soil samples collected from borings or test pits in 1998. In 1998, six additional soil samples (SS- 11a, SS-11b, SS-12, SS-12c, TR-01a, and TR-01b) were collected from borings and test pits at three locations at the IAA. Samples SS-11a and SS-11b were collected adjacent to Building 8102-5, samples SS-12 and SS-12c were collected adjacent to Building 8102-6 and Samples TR-01a and TR-01b were collected adjacent to the former transformer located north of Building 8102-4. A total of seven surface soil samples were collected and analyzed as follows:

- Two surface soil samples for VOCs
- Four surface soil samples for SVOCs
- Four surface soil samples for PCBs
- Four surface soil samples for Pesticides
- Five surface soil samples for TAL inorganics;
- One surface soil sample for asbestos

Igniter Assembly Area

Additionally, one paint chip sample (WS-03) from the conductive flooring was collected and analyzed for TAL inorganics.

The laboratory analytical results are summarized in Table 7-3 and the sample locations are depicted in Figure 7-2. The results indicated the following:

VOCs. Acetone, methylene chloride, and naphthalene were detected in two surface soil samples (SS-03 and SS-11). The detected concentrations were several orders of magnitude below applicable residential RSLs (see Table 7-3). No other VOCs were detected during this event.

SVOCs. A total of nineteen SVOCs were detected in various soil samples during this event (see Table 7-3). Five of the SVOCs [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene] were detected at concentrations above industrial RSLs at soil sample TR-01A. Soil sample TR-01b, which was collected immediately adjacent to TR-01a only contained benzo(a)pyrene at a concentration above the residential RSL. Benzo(a)pyrene and benzo(b)fluoranthene were also detected at concentrations above the residential RSL at sample location SS-11. The other SVOCs detected during this event were at concentrations below applicable industrial and residential RSLs.

PCBs. Aroclor 1260 was the only PCB detected during this sampling event. Aroclor 1260 was detected at a concentration above the industrial RSL in one soil sample (SS-03) and between the residential and industrial RSLs in one soil sample (SS-03) (see Table 7-3). PCBs were not detected in samples TR-01A and TR-01B collected adjacent to the former transformer location.

Pesticides. One pesticide (Endrin) was detected at sample location TR-01 (see Table 7-3). The detected concentration was below the residential RSL. No other pesticides were detected in the soil samples.

Inorganics. Several inorganic constituents were detected in all of the soil samples collected during this investigation (see Table 7-3). Three inorganics were detected at concentrations above both industrial RSLs and established background concentrations in at least one soil sample, including:

- Arsenic in all soil samples analyzed for TAL metals (SS-03, SS-11, SS-11a, SS-11b, and SS-12) and in the paint chip sample WS-03

- Copper in all soil samples analyzed for TAL metals and in the paint chip sample WS-03
- Cobalt in soil samples SS-11 and SS-12
- Lead in soil samples SS-11 and SS-11a

Five inorganics were also detected at concentrations between the residential and industrial screening levels and natural background concentrations in at least one soil sample, including:

- Barium in soil samples SS-11, SS-11a, SS-11b, and SS-12
- Cadmium in soil sample SS-11
- Nickel in soil sample SS-12
- Zinc in soil samples SS-11, SS-11a, SS-11b, and SS-12 and the paint chip sample WS-03

Asbestos. Asbestos (chrysotile) was detected in one soil sample (SS-12) at 2.1% (see Table 7-3).

7.4.4 Remedial Investigation, ICF KE, 1998

The purpose of the 1998 RI was to further characterize the nature and extent of target constituents at the IAA through the investigation of surface/subsurface soil and conductive flooring. Activities completed during this investigation included:

- The advancement of test pits adjacent to Buildings 8101-1 and 8101-7 to characterize the soil profile and assess the nature and extent of contamination due to the runoff of conductive flooring material from the buildings. Four surface soil samples and four subsurface soil samples were collected as part of the test pitting activities.

- Five soil borings (IASB1 through IASB5) in various areas of the IAA. Five surface soil samples [IASB1 (0.5-1), IASB2 (0-2), IASB3 (0.5-1), IASB4 (0.5-1.5), and IASB5 (0.5-1)] and five subsurface soil samples [IASB1 (5-6), IASB2 (4-6), IASB2 (26-28), IASB3 (5-6), IASB4 (5-6), IASB5 (0.5-6)] were collected from these soil borings.

- One conductive floor sample (IACF2) was collected from the northeast corner of Building 8102-1.

7.4.4.1 1998 Test Pitting Activities

Two 6 x 2 ft test pits (IATP1 and IATP2) were advanced to a depth of 4 ft on the northeast corner of Buildings 8102-1 and 8102-7, respectively. These test pits were advanced to characterize the soil profile and assess the nature and extent of constituent detections due to the runoff of conductive flooring material from the buildings. A substantial quantity of red-stained surface soil was encountered in the immediate vicinity of both buildings. Field observations during the advancement of test pit IATP1 indicated that red-stained soil was visible to a distance of 2.5 ft from the building foundation and to a depth of approximately 1.2 ft bgs. Field observations at test pit IATP2 indicated that the red-stained soil extended to nearly 3 ft from the building foundation to a depth of 0.5 ft bgs. The soil physical characteristics and the discovery of fill material, encountered during the advancement of IATP2, indicated that soil directly surrounding Building 8102-7 is not native. However, the soil physical characteristics encountered during the advancement of test pit IATP1 were indicative of native soil.

Samples were collected from both test pits. Test pit samples IATP1A and IATP1C were collected a distance of approximately 1 ft and 5 ft from the foundation of Building 8102-1, respectively, at a depth of 0.5-1.0 ft bgs. Samples IATP1B and IATP1D were collected at the same locations as IATP1A and IATP1C at depths of 4.0-4.5 ft bgs. The same strategy was utilized for soil samples (IATP2A through IATP2D) collected from test pit IATP2. The soil samples from both test pits were analyzed for explosives and TAL inorganics. The surface soil samples were also analyzed for TCL SVOCs. The analytical results from the test pit samples are summarized in Table 7-4 and the sample locations are depicted in Figure 7-2.

SVOCs. A total of eleven different SVOCs were detected in various test pit soil samples (See Table 7-4). Benzo(a)pyrene was detected at a concentration of 0.080 mg/kg at IATP1A, which is above the residential RSL but below the industrial RSL. No other SVOC/PAH constituents were detected at concentrations above applicable RSLs.

Explosives. No explosives were detected in any of the test pit samples.

Inorganics. As with all samples at the RFAAP-NRU, several inorganics were detected in all of the test pit soil samples (see Table 7-4). Arsenic (28.8 mg/kg) and copper (7,070 mg/kg) were detected in surface soil sample IATP2A at concentrations above established background concentrations and industrial RSLs. The other surface soil sample from test pit ITAP2 (IATP2B) had copper present at a concentration of 1,440 mg/kg, which is above the residential RSL and background. The subsurface soil samples from the IATP2 test pit did not have any inorganics detected at concentrations above background levels. The only constituent detected above background in the IATP1 test pit was copper in surface soil sample IATP1A. Copper was detected in this sample at a concentration of 1,280 mg/kg, which is above the residential RSL.

7.4.4.2 1998 Soil Borings

In addition to the test pit samples, eleven soil samples were collected from five borings (IASB1, IASB2, IASB3, IASB4, and IASB5) located adjacent to Buildings 8102-2, 8102-3, 8102-4, 8102-6, and 8102-7 respectively. Boring IASB4 was located at previous location SS-12, where the highest concentrations of copper and arsenic were detected by Gannett Fleming in 1998. A shallow sample (0-2 ft bgs) and a medium depth sample (4-6 ft bgs) were collected from each boring. Additionally, one deep sample [IASB2C] was collected from a depth of 26-28 ft bgs to characterize the lower subsurface region. All eleven samples were analyzed for SVOCs and inorganics. One sample [IASB5B (4-6 ft bgs)] was also analyzed for explosives. The analytical results from these samples are also summarized in Table 7-4 and the sample locations are depicted in Figure 7-2. The results indicated the following:

SVOCs. Seven different SVOCs/PAHs were detected in isolated soil samples during this event (See Table 7-4). The detected constituents were all at concentrations lower than applicable industrial and residential RSLs.

Explosives. No explosive compounds were detected in soil sample IASB5B (4-6 ft bgs).

Inorganics. Several inorganics were detected in all of the soil samples collected during this event (see Table 7-4). Iron was detected in surface soil sample IASB3 (0.5-1 ft bgs) at a concentration of 52,600 mg/kg, which is above the residential RSL, and slightly above the background level of 50,962 mg/kg. No other inorganics were detected in surface or subsurface soil at concentrations above background and residential RSLs.

7.4.4.3 1998 Conductive Flooring Sample

One conductive floor sample (IACF2) was collected from the northeast corner of Building 8102-1 to verify floor material composition and assess transport and mobility.

Igniter Assembly Area

A small chunk of the red conductive flooring material was collected from the surface of the building foundation and was considered representative of the material found in each of the buildings. The flooring was a dry, dull red colored material containing white fibers. The sample was analyzed for TCL SVOCs, TCLP inorganics, and asbestos. Results of the conductive flooring analysis are summarized in Table 7-5. TCLP results indicate that barium, cadmium, chromium, lead, and selenium were present in leachable forms in the conductive floor sample. None of the detected inorganics were at concentrations above their respective TCLP regulatory guidelines. Asbestos and TCL SVOCs were not detected in the flooring sample.

7.4.5 Conductive Flooring Assessment, USACE, 2002

The USACE completed a conductive flooring assessment in 2002 to further evaluate the composition of the conductive flooring material at the IAA and the BLA. The results of this investigation are summarized in the 2003 report entitled *Site Screening Report of Conductive Flooring at the Igniter Assembly Area and Bag Loading Area in the New River Unit* (USACE, 2003). The sampling activities at the IAA included the collection of flooring samples from 14 buildings [Buildings 502, 504, 509, 522, 529, 8102-A (a loading dock located to the north of Building 8102-8), 8102-2, 8102-7, Building XXXX (located between Buildings 522 and 529), 1, 562, 565, and 571].

Fifteen conductive flooring samples (two from Building 8102-7, one from each of the remaining buildings) were collected from buildings in the IAA to verify floor material composition and assess transport and mobility. A small chunk of the red conductive flooring material was collected from the surface of the building foundation. The flooring is a dry, dull red colored material containing white fibers. The samples were analyzed for TCL VOCs, TCL SVOCs, PCBs, TCL pesticides, explosives, and asbestos. In addition, one sample, was analyzed for TCLP VOCs and TCLP metals. The laboratory analytical results are summarized in Table 7-6. The results indicated the following:

VOCs. Two VOCs (acetone and methylene chloride) were detected in conductive flooring samples. The detected concentrations were all below applicable industrial and residential soil RSLs.

SVOCs. Fourteen different SVOCs/PAHs were detected in the conductive flooring samples (see Table 7-6). However, the detected concentration of the PAH benzo(a)pyrene in the sample from Building 509, was the only constituent detected at a concentration above the industrial RSL. Two other PAHs [benzo(a)anthracene and benzo(b)fluoranthene] were also detected above the residential RSL in the sample from Building 509, No other PAHs were detected at concentrations above residential RSLs in any of the conductive flooring samples.

PCBs. The PCB Aroclor 1254 was detected in samples from Buildings 504, 509, 522, and 529 at concentrations above industrial soil RSLs. Aroclor 1254 was also detected in samples from Buildings 502 and XXXX at concentrations between the residential and industrial soil RSLs. With the exception of Aroclor 1232 at Building 502, which was detected at a concentration below the residential RSL, no other PCBs were detected during this sampling event.

Pesticides. Six different pesticides (4,4'DDE, 4,4'DDT, dieldrin, endrin, lindane, and gamma chlordane) were detected in isolated samples during this event (see Table 7-6). Dieldrin was detected at concentrations above the residential RSL in three of the conductive flooring samples (RFAAP-502, RFAAP-522, and RFAAP-529. No other pesticides were detected above residential RSLs in the conductive flooring samples.

Explosives. No explosives were detected in any of the conductive flooring samples.

Inorganics. Several inorganics were detected in all of the flooring samples collected during this sampling event (see Table 6-6). Arsenic, copper, and lead were all detected in several samples at concentrations above background soil concentrations and industrial soil RSLs. Chromium, nickel, and zinc were also detected in several samples at concentrations above background and residential soil RSLs.

Asbestos. Asbestos (chrysotile) was detected at low concentrations (approximately 2 percent) in all of the conductive flooring samples (see Table 7-6).

TCLP VOCs and TCLP Metals. The VOC tetrachloroethylene (PCE) was the only constituent detected in leachable form in the sample analyzed for TCLP VOCs and TCLP metals. The detected concentration was lower than the TCLP disposal standard of 700 µg/L (see Table 7-6).

The conclusions of the investigation indicated that the composition of the conductive flooring was generally consistent among all buildings at the IAA.

7.4.6 Site Investigation, Shaw, 2002.

This section is intended to provide a brief summary of the field activities conducted at the IAA by Shaw during the 2002 field investigation. The field activities included the following:

- Five surface soil samples (IASS01 through IASS05) were collected from areas located adjacent to IAA buildings.
- Ten additional surface soil samples and 15 subsurface soil samples were collected from ten borings (IASB06 through IASB15) located adjacent to buildings with conductive flooring.
- Eight surface soil samples (IATR01 through IATR08) were collected from test pits completed at former transformer locations.
- Nine sediment samples (IASD04 through IASD12) were collected from area drainage ditches.

7.4.6.1 Soil Sampling

A total of 15 surface soil samples and 15 subsurface soil samples were collected next to the IAA buildings during the 2002 investigation. All of the soil samples were analyzed for TAL inorganics. Other analyte classes sampled for in this investigation included VOCs, PAHs/SVOCs, PCBs, pesticides, herbicides, explosives, pH, and grain size; however, not all analytes were included at every location. The laboratory analytical results from this sampling event are summarized in Table 7-7, and the sample locations are depicted in Figure 7-2. The results indicated the following:

VOCs. Two VOCs (acetone and toluene) were detected in isolated samples at concentrations several orders of magnitude below applicable residential RSLs (see Table 7-7).

SVOCs. Twenty different SVOC/PAH constituents were detected in the surface soil sample at sample location IAASS05 (see Table 7-7). The analytical results indicated that the concentration of benzo(a)pyrene was higher than the industrial RSL at this location. Benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were also detected at this location at concentrations above the residential RSL. The other detected constituents were at concentrations lower than residential RSLs.

PAHs. A total of 17 PAH constituents were detected in isolated surface and subsurface soil samples (see Table 7-7). The analytical results indicated that no constituents were at concentrations higher than industrial RSLs. Benzo(a)pyrene was detected at a concentration higher the residential RSL at sample location IASS05 (this is the same sample location that had several PAH constituents at concentrations above applicable RSLs in the SVOC analysis). No other PAHs were detected at concentrations above applicable RSLs.

PCBs. The PCB Aroclor 1254 was detected above the industrial RSL in sample IASS05, which was collected adjacent to Building 8101 (this building did not contain conductive flooring). PCBs were not detected in any of the other surface or subsurface soil samples collected next to IAA buildings during this event (see Table 7-7).

Pesticides. Pesticides were not detected in the one surface soil sample (IASB06) collected for pesticide analysis.

Herbicides. No herbicides were detected the one surface soil sample (IASB06) collected for herbicide analysis.

Explosives. The explosive nitroglycerine was detected at soil sample location IASS05 at a concentration of 0.57 mg/kg (see Table 7-7). The detected concentration was below the residential RSL of 0.61 mg/kg. No other explosives were detected.

Inorganics. Several inorganic constituents were detected in all of the soil samples collected during this sampling event (see Table 7-7). Arsenic at IASB12 (4-6 ft bgs), lead at IASB14 (0-0.5 ft bgs), and cobalt at IASB07 (0-0.5 ft bgs)were the only constituents detected at concentrations above background levels and industrial RSLs. Aluminum, copper, iron and lead were also detected in various samples at concentrations above background levels and residential RSLs.

The eight surface soil samples collected from the former transformer locations (IATR01 through IATR08) were analyzed for PCBs. The analytical results for these samples are summarized in Table 7-7 and the sample locations are depicted in Figure 7-2. The results indicated that sample location IATR07 was the only location that contained a PCB detection. Aroclor 1260 was detected at a concentration of 0.40 mg/kg at IATR07, which is above the residential RSL of 0.24 mg/kg.

7.4.6.2 Sediment Sampling

Nine sediment samples (IASD04 through IASD12) were collected from IAA area drainage ditches during the 2002 investigation. The ditches were all dry during the sampling event and only carry water during heavy rainfall events. The samples were analyzed for VOCs, PAHs/SVOCs, PCBs, pesticides, herbicides, explosives, and TAL inorganics. One sediment sample (IASD12) was also analyzed for TOC and pH. The laboratory analytical results from this sampling event are summarized in Table 7-8, and the sample locations are depicted in Figure 7-2. The results indicated the following:

VOCs. Two VOCs (acetone and toluene) were detected in a limited number of sediment samples (see Table 7-8). The detected concentrations were several orders of magnitude below applicable industrial and residential RSLs. No other VOCs were detected in any of the samples.

SVOCs/PAHs. Twenty one SVOCs were detected in sediment samples (see Table 7-8). Five SVOCs [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene] were detected at concentrations above their respective industrial RSL in sample IASD09. Benzo(a)pyrene was also detected above its industrial RSL at IASD10. These samples (IASD9 and IASD10) were not analyzed by the more sensitive PAH method. The IASD09 and IASD10 samples were collected from culverts that pass under a paved road in the southern portion of the IAA. Benzo(a)pyrene, benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were also detected in a limited number of samples at concentrations above applicable residential RSLs.

PCBs. PCBs were not detected in any of the sediment samples.

Pesticides. Thirteen different pesticides were detected in various sediment samples (see Table 7-8). However, all of the detected concentrations were below applicable residential RSLs.

Herbicides. No herbicides were detected in any of the sediment samples.

Explosives. The explosive 1,3,5-trinitrobenzene was detected at a concentration of 0.07 mg/kg at IASD11 and 4-amino-2,6-dinitrotoluene was detected at a concentration of 0.04 mg/kg at IASD05. Neither of the detected concentrations were above applicable residential RSLs. No other explosives were detected in any of the samples.

Inorganics. Several inorganics were detected in all of the sediment samples included in the event (see Table 7-8). However, lead was the only inorganic detected at concentrations above applicable RSLs and established background levels. The sediment sample collected at IASD06 contained lead at a concentration of 884 mg/kg, which is above the industrial RSL of 800 mg/kg. The sediment sample collected at IASD12 contained lead at a concentration of 643 mg/kg, which is above the residential RSL of 400 mg/kg. These sample locations were both in culverts that receive rain water runoff from the central portion of the IAA.

7.4.7 Asbestos and Lead Investigation, Shaw, 2005

Shaw completed an asbestos and lead based paint survey at the IAA during 2005. This event included the collection of the following samples:

- Nine soil samples (BPASS01, BPASS02, BPASS03, and IASS06 through IASS11) were collected for asbestos analysis
- Three samples of deteriorated conductive flooring material (BPADF01, IADF01, and IADF02) for asbestos analysis
- Three samples of intact conductive flooring material (BPAIF01, IAIF01, and IAIF02) for asbestos analysis
- One sample of the building wall material (IAWM01) for asbestos analysis
- Three wipe samples (IAW01, IAW02 and IAW03) for total asbestos analysis
- Three paint chip samples (IAPC01, IAPC02, and IAPC03) from IAA buildings for lead analysis

The exact locations of the samples collected during this event were not recorded. However, sample locations as described in this report have been inferred based on a February 2005 Draft Field Sampling Plan by Shaw. Sample labels starting with BPA were collected at, or in the vicinity of, Building 570 in the black powder area of the IAA. The soil samples (IASS06 through IASS11) were collected in the vicinity of previous soil samples SS-11 and 504312012 (0-1 ft bgs). The conductive flooring samples (IADF02, IADF01, IAIF01, and IAIF02) were collected from Buildings 8102-5 and 504. The laboratory analytical results for the soil samples are presented in Table 7-9**.** The laboratory analytical results for the conductive flooring samples and paint chip samples are presented in Table 7-10.

The results of the asbestos analysis indicated that the chrysotile was the only asbestos type detected. Total asbestos concentrations detected in the soil samples ranged from non-detect to 1.9% in the samples collected around Building 507. The asbestos concentrations detected in the soil samples in other areas of the IAA ranged from 0.1 % to15%. Asbestos concentrations in the intact flooring material ranged from 13.6% to 23.7% and from 7.1% to 16% in the deteriorated flooring.

The results from the paint chip samples indicated that lead concentrations ranged from 1,100 mg/kg to 49,500 mg/kg. Very little paint remains on the IAA buildings.

7.4.8 RI Investigation, ARCADIS 2008

In accordance with Remedial Investigation Work Plan Addendum 27 (ARCADIS 2008b), ARCADIS completed additional investigation activities at the IAA in 2008 to finalize the characterization and delineation work at this site. The primary goal of the 2008 investigation was to complete the delineation of inorganics and asbestos in surface soils around buildings containing conductive flooring. The investigation also included the collection of samples to delineate historical PCB and PAH detections near Building 8101, and lead detections in area drainage pathways. One water sample was also collected from a utility vault below Building 522. The investigation activities and results for these areas are discussed in the following sections

7.4.8.1 2008 Building Area Investigation Activities

The primary goal of ARCADIS' 2008 investigation was to delineate the extent of inorganics and asbestos detections in surface soil surrounding buildings with conductive flooring material. Following is a summary of the investigation activities performed to complete this assessment:

- ARCADIS performed an inventory of the buildings at the IAA to identify buildings with conductive flooring, including those that may not have appeared on historic site maps. The locations of all buildings were surveyed utilizing GPS equipment and measurements were collected of the building dimensions. All buildings at the IAA are depicted in Figure 7-1. The building inventory identified 29 buildings with conductive flooring material. In total approximately 25,000 ft^2 of conductive flooring material is present at the site.

- Review of the analytical data collected during the previous investigations of the IAA indicated that lead could be used as a good predictor of where other constituents may also be present in surface soil at concentrations above applicable screening criteria as a result of the deteriorating conductive flooring. Therefore, ARCADIS developed a field screening program that utilized a hand-held XRF meter to screen surface soil samples for lead. Samples were typically collected in rows of three screening points spaced at 1 ft, 5 ft, and 10ft distances from the building footprint. In cases where the XRF result indicated a lead concentration above 400 mg/kg, the samples were also collected further away from the building (i.e., 15 ft and 20 ft). The rows were located on approximately 25 ft centers around the perimeter of each building, with a bias towards preferential flow paths off of the building pads (i.e., where red staining was present in soil). A total of 157 rows containing 475 individual points (IAA-R1A through IAA-R157C) were screened with the XRF around the perimeters of buildings identified with conductive flooring. The field screening locations are depicted in Figure 7-3. The screening points were identified with the letter R for Row followed by a number (001 through 157) representing the row number where the screening point was located, followed by a letter (A, B, C, D, or E) representing the distance from the building pad to the sample location (1, 5, 10, 15, 20 ft, respectively).

- In order to evaluate the results of the XRF screening results and to provide additional characterization data, duplicate samples were collected from 41 of the 475 XRF screening locations. A minimum of one sample was collected at each building identified with conductive flooring. These samples (IAA-SS003 through IAA-SS043) were submitted for laboratory analysis of TAL inorganics and asbestos. Five of these samples (IAA-SS009, IAA-SS021, IAA-SS028, IAA-SS033, and IAA-SS043) were also submitted for laboratory analysis of TCLP-inorganics. The sample locations are depicted in Figure 7-2. Comparison of the XRF field screening results generally indicated a positive correlation between the XRF results and the results of the laboratory reported lead concentrations; with the XRF results typically biased slightly high. Figure 7-7 presents a graphical comparison between the XRF and laboratory results.

7.4.8.2 XRF Lead Screening Results

The results of the XRF lead screening activities at the IAA buildings are summarized in Table 7-11. The results of the XRF screening are also presented in Figure 7-3A and 7-3B. The XRF screening activities indicated the following:

- The XRF screening results indicated that lead concentrations were above industrial RSLs in 49 of the 475 field screening locations. There were also 11 locations where the detected lead concentration was between the residential and industrial RSL. Figure 7-4 illustrates the distribution of the detected lead concentrations during the XRF field screening program. A total of 49 of the 60 screening locations that had lead concentrations above the RSLs occurred at 4 site buildings (Buildings 502, 504,522, and 522A) located in the southern portion of the IAA. Field observations indicated that these buildings were surrounded by a significant amount of gravel debris that may have influenced the XRF results.

- Lead was detected at the following buildings at concentrations above applicable RSLs
    - **Building 8102-3 –** Three screening locations at Building 8102-3 (IAA-R45A, IAA-R46A, and IAA-R51A) had lead detections above the industrial RSL. The detected lead concentrations in these samples, all of which were collected 1-ft away from the building pad, ranged from 970 mg/kg to 1,340 mg/kg (see Table 7-11). All of the other screening locations at this building had lead concentrations below the residential screening level.
    - **Building 8102-4** – Lead was detected at a concentration of 1,185 mg/kg screening location IAA-R39A and 487 mg/kg at screening location IAA-R38A. Both samples were collected 1-ft away from the building pad (see Table 7-11). All of the other screening locations at this building had lead concentrations below the residential screening level.
    - **Building 502** – Building 502 is located in the southern portion of the IAA. The field screening results for the samples collected around this building indicated that lead concentrations were above the industrial RSL in 21 separate sample locations on the northeast (IAA-R112A through IAA-R113C), southeast (IAA-R114A through IAA-R114C), and southwest (IAA-R115A through IAA-R117C) sides of the building. The detections above the RSL extended up to 15-ft from the building pad. XRF reported lead concentrations ranged from 291 mg/kg to 50,000 mg/kg on these sides of the building (see Table 7-11). The XRF reported lead concentrations around this building may have been influenced by the presence of a large amount of gravel debris in the soil.
    - **Building 504** – Building 504 is located adjacent to Building 502 in the southern portion of the IAA. Like Building 502, many of the XRF

Igniter Assembly Area

readings collected around this building were elevated in comparison to other areas of the site. Eleven of the 24 screening locations resulted in lead concentrations above the industrial RSL (see Table 7-11). The XRF lead concentrations in these eleven samples ranged from 857 mg/kg to 16,597 mg/kg. Three additional locations had lead concentrations reported between the residential RSL and the industrial RSL. Unlike Building 502, the detections above the RSL generally were confined to soils within 5-ft of the building pad. The XRF reported lead concentrations around this building may also have been influenced by the presence of a large amount of gravel debris in the soil.

- **Building 522** – Building 522 is located in the southern portion of the IAA, north of Building 504. Four screening locations (IAA-R83A and IAA-R85A through IAA-R85C) had reported lead concentrations above the industrial RSL. Four other samples (IAA-R80A, IAA-R81A, IAA-R82A, and IAA-R86A), all collected within 1-ft of the building pad, contained lead concentrations above the residential RSL (see Table 7-11).

- **Building 522A** – Building 522A is located adjacent to Building 522A. Four of the samples collected from a distance of 1-ft from the building pad (IAA-R88A, IAA-R89A, IAA-R90A, and IAA-R93A) contained XRF reported lead concentrations above industrial RSL. In addition, two samples (IAA-R90B and IAA-R92A) had concentrations reported above the residential RSL (see Table 7-11).

- **Building 4** – Building 4 is located in northwest portion of the IAA. One screening location at this building (IAA-R123A) resulted in a lead concentration above the residential RSL (see Table 7-11). All of the other screening locations at this building were below the residential RSL. .

- **Building 5** – Building 5 is also located in northwest portion of the IAA. Three screening locations at this building, IAA-R126A, IAA-126B, and IAA-126C resulted in lead concentrations of 1,046 mg/kg, 885 mg/kg, and 1,425 mg/kg, respectively. These samples were all collected from one row on the southwest side of the building, at a distance extending out to 10-ft from the building pad. A fourth sample from this row, collected 15-ft from the building resulted in a concentration of 121 mg/kg, which is below the residential RSL. None of the other screening locations at this building contained lead at concentrations above the residential RSL (see Table 7-11).

- **Building 562** – Building 562 is located in northeast portion of the IAA. One screening location at this building (IAA-R137A) resulted in a lead concentration of 2,695 mg/kg. This sample was collected 1-ft away from the building pad. All of the other screening samples collected at this building had lead concentrations below the residential RSL (see Table 7-11).

- **Building 565B** – Building 565B is located in northeast portion of the IAA. One screening location at this building (IAA-R149A) resulted in a lead concentration of 945 mg/kg. This sample was collected 1-ft away from the building pad. All of the other screening samples collected at this building had lead concentrations below the residential RSL (see Table 7-11).

7.4.8.3 IAA Inorganics and Asbestos Sampling

ARCADIS collected soil samples at 41 of the 475 XRF field screening locations to evaluate the results of the XRF field screening and to provide additional characterization of the surface soils. At least one sample was collected at each of the 29 conductive flooring buildings at the IAA. These samples (IAA-SS003 through IAA-SS043) were submitted for laboratory analysis of TAL inorganics and asbestos. Five of these samples (IAA-SS009, IAA-SS021, IAA-SS028, IAA-SS033, and IAA-SS043) were also submitted for laboratory analysis of TCLP-inorganics. The sample locations are depicted in Figure 7-2, and the laboratory analytical results are summarized in Table 7-12. The laboratory analytical reports for the 2008 sampling activities are included in Appendix E. The laboratory analytical results indicated the following:

- Lead was detected at concentrations above the industrial RSL in eight of the 41 samples, and above the residential RSL in two other samples. Figure 7-5 illustrates the distribution of the lead concentrations detected in the laboratory samples during the 2008 sampling event. All but one of the samples that had a concentration above an applicable RSL (IAA-SS014) corresponded with an XRF reading that was also above the industrial RSL.

- In general, the detected lead concentrations were very comparable with the XRF readings; although, the XRF readings were typically biased slightly high compared to the laboratory detected concentration. These data indicate that the XRF field analysis was a good screening tool for identifying areas with lead concentrations above applicable RSLs. See Table 7-12 for comparison between the XRF screening results and the laboratory analytical results. Figure 7-6 also presents a graphical comparison of the XRF and laboratory lead results..

- Six of the samples (IAASS026, IAA-SS027, IAA-SS028, IAA-SS029, IAA-SS032, and IAA-SS033) that had lead detections above applicable RSL were collected in the southern portion of the IAA, near Buildings 502, 504, and 522. The XRF readings had also indicated that elevated lead concentrations were present in this area. The other samples that had lead detections above applicable RSLs included:

    - IAA-SS009 (1,170 mg/kg) was collected in the sample location spaced 1-ft from Building 8102-3

    - IAA-SS012 (14,400 mg/kg) was collected in the sample location spaced 1-ft from Building 8102-4

    - IAA0SS014 (567 mg/kg) was collected in the sample location spaced 5-ft from Building 8102-5

    - IAA-SS017 (6,160 mg/kg) was collected in the sample location spaced 5-ft from Building 8102-6

- Copper was the inorganic most frequently detected at concentrations above applicable RSLs (see Table 7-12). Of the 41 samples collected during this event, 20 samples had copper detected at concentrations above the residential RSL (310 mg/kg) and background levels (53.5 mg/kg). The concentrations in six of these samples also were above the industrial RSL (4,100 mg/kg). The maximum copper concentration (14,600 mg/kg) was detected in sample IAA-SS022 located approximately 5-ft from Building 8102-8. Lead was also detected above the RSL at this location. The samples that had copper detections above the industrial RSL (IAA-SS006, IAA-SS009, IAA-SS022, IAASS025, IAA-SS033, and IAA-SS041) were all located within 1-ft of a building foundation. The results indicate that copper concentrations were generally lower in the samples collected 5-ft and 10-ft away from buildings.

- Arsenic was detected above the established background concentration (15.8 mg/kg) and above the industrial RSL (1.6 mg/kg) in ten of the 41 soil samples collected in 2008 from the IAA (see Table 7-12). The maximum arsenic concentration (62.9 mg/kg) was detected in sample IAA-SS029 located approximately 5-ft from Building 502.

- Barium was detected above the established background concentration of 209 mg/kg in 15 of the 41 sample locations (see Table 7-12). However, the detected concentrations were only above the residential RSL of 1,500 mg/kg in five of the samples (IAA-SS009, IAA-SS012, IAA-SS022, IAA-SS025, and IAA-SS033). The maximum detected barium concentration (5,740 mg/kg) occurred in sample IAA-SS009 located approximately 1-ft from Building 8102-3. All of the barium concentrations above the residential RSL were collected within 1-ft of a building foundation.

- Cadmium was detected above the established background concentration (0.69 mg/kg) and above the residential soil RSL (7 mg/kg) in two of the 41 soil samples collected in 2008 from the IAA (see Table 7-12). Cadmium was not detected above the industrial soil RSL (81 mg/kg) in any samples. Both locations that had cadmium detections above the residential RSL, IAA-SS015 (15.2 mg/kg) and IAA-SS033 (9.20 mg/kg), were located within 1-ft of a building foundation.

- Chromium was detected above the established background concentration (65.3 mg/kg) and above the residential soil RSL (23 mg/kg) in two samples (IAA-SS026 and IAA-SS028) (see Table 7-12). These samples were collected in the southern portion of the IAA, near buildings 502 and 504,. The maximum chromium concentration (1,110 mg/kg) was detected in sample IAA-SS026, located approximately 5 ft from Building 504. This sample also contained elevated concentrations of copper, iron, lead, and zinc.

- Iron was detected above the established background concentration (50,962 mg/kg) and above the residential soil RSL (5,500 mg/kg) in three of the 41 soil samples collected in 2008 from the IAA (see Table 7-12). However iron was not detected above the industrial soil RSL (720,000 mg/kg) in any samples.

The maximum iron concentration (328,000 mg/kg) was detected in sample IAA-SS028 located approximately 5-ft from Building 502.

- Mercury was detected at concentrations above the background level (0.13 mg/kg) in 7 of the 41 samples from the IAA area (see Table 7-12). However, sample IAA-SS022 (79.5 mg/kg) was the only sample that contained mercury at a concentration above the industrial RSL. IAA-SS022 was located approximately 1-ft from the building pad at Building 8102-8. None of the other detected mercury concentrations were above applicable RSLs.

- Nickel was detected at a concentration of 213 mg/kg at sample location IAA-SS028, which was collected 5-ft away from Building 502 (see Table 7-12). This concentration was above the established background nickel concentration of 62.8 mg/kg and the residential RSL of 160 mg/kg. Arsenic, chromium, copper, iron, and lead were also detected above applicable RSLs and background at this location. Nickel was not detected above the background level in any of the other soil samples collected at the IAA in 2008.

- Zinc was detected above the established background concentration of 202 mg/kg in 21 of the 41 sample locations (see Table 7-12). However, the detected zinc concentrations were only above the residential RSL in 4 of the 41 samples (IAA-SS006, IAA-SS009, IAA-SS012, and IAA-SS022). These samples were all collected from locations approximately 1-ft away from buildings in the central portion of the IAA. The maximum zinc concentration (6,430 mg/kg) was detected in sample IAA-SS009 located adjacent to Building 8102-3.

- Previous sampling efforts at the IAA had identified the type of asbestos at the site to be chrysotile. The soil samples collected during ARCADIS 2008 sampling event only identified whether or not asbestos was present in the soil. (i.e., yes/no). The results of the 2008 investigation indicated that 20 of the 41 soil sample locations contained asbestos (see Table 7-12). Fifteen of the samples that contained asbestos were collected within 1-ft of buildings containing conductive flooring material. The other samples containing asbestos were collected within 5-ft of a building.

- The results of the TCLP analysis performed on the five soil samples indicated that arsenic, barium, cadmium, chromium, and lead were detected (see Table

7-12). However, the detected concentrations were all below applicable TCLP screening levels.

7.4.8.4 Building 8101 Area Sampling

The analytical results from a sample collected near Building 8101 in 2002 (IASS05) indicated that Aroclor 1254 and benzo(a)pyrene were present in surface soil at concentrations above industrial RSLs. In order to complete the delineation of these constituents, ARCADIS collected two surface soil samples (IAA-SS001 and IAA-SS002) and one subsurface soil sample (IAA-SB001) near the historical IASS05 sample location (see sample locations in Figure 7-2). The surface and subsurface samples were analyzed for PCBs and SVOCs. The analytical results from these samples are summarized in Table 7-12. The results indicated that surface soil sample IAA-SS002 contained benzo(a)pyrene, benzo(a)anthracene, and benzo(b)fluoranthene at concentrations above residential RSLs. The results also indicated that the Aroclor 1254 was detected at IAA-SS002 (0.090 mg/kg), but that the concentration was below residential RSLs. PAHs and PCBs were not detected at sample locations IAA-SB001 or IAA-SS001.

7.4.8.5 Drainage Ditch Sampling

Laboratory analytical results from Shaw's 2002 sampling event indicated that lead was detected at concentrations above applicable RSLs in samples collected from two IAA area drainage ditches Lead was detected at IASD06 (northeast of Building 8102-1) at a concentration of 884 mg/kg, which is above the industrial RSL. Lead was also detected at sample location IASD12 (northeast of Building 8102-5) at a concentration of 643 mg/kg which is above the residential RSL. In an effort to evaluate the extent of the elevated lead concentrations in the two IAA drainage pathways, ARCADIS collected the following samples for field screening and laboratory analysis during 2008.

- Three samples were selected for field screening using XRF near the 2002 IASD06 sample location (IAA-SE007X through IAA-SE009X). Two samples (IAA-SE001 and IAA-SE002) were also submitted for laboratory analysis of inorganics from this drainage pathway.

- Six samples were collected from the drainage pathway downgradient of the 2002 IASD06 sample location (IAA-SE001X through IAA-SE006X) for field screening using XRF. Two samples (IAA-SE003 and IAA-SE004) were also submitted for laboratory analysis of inorganics from this drainage pathway.

The results of the field screening and laboratory analytical samples are summarized in Tables 7-11 and 7-13, respectively. The field screening sample locations are depicted in Figures 7-3A and 7-3B and the samples submitted for laboratory analysis are depicted in Figure 7-2. The results of both the field screening and laboratory samples indicated that the lead concentrations in both drainage pathways were only slightly above background and were well below residential RSLs. No other inorganics were detected in the samples at concentrations above background levels. The sample results appear to indicate that lead is not a concern in the drainage pathways.

7.4.8.6 Utility Vault Sampling

An underground, concrete, utility vault was identified at Building 522 that appears to run around the perimeter of the building. Standing water was present in this vault that was approximately 2 ft deep. No sediment was present at the bottom of the vault. A sample of the vault water (IAA-VLTW01) was collected for laboratory analysis of VOCs, PAHs, and TAL metals (see Figure 7-2 for sample location). The analytical results from this sample are summarized in Table 7-14. The results indicated that no constituents were detected at concentrations above tap water RSLs.

7.4.9 Supplemental RI Investigation, ARCADIS 2009

In accordance with the June 2009 Supplemental Remedial Investigation Work Plan (ARCADIS 2009b), ARCADIS completed additional investigation activities at the IAA in 2009. The goals of the 2009 investigation were to: 1) enhance the delineation of asbestos in surface soils around buildings containing conductive flooring; and 2) to evaluate potential airborne asbestos exposure risks associated with the asbestos in soil. Both soil and air samples were collected and analyzed for asbestos during this investigation. The investigation activities and results for these areas are discussed in the following sections.

7.4.9.1 Asbestos Delineation Sampling

ARCADIS' 2008 sampling activities at the IAA indicated that asbestos was present in surface soil adjacent to several buildings with conductive flooring. However, the analytical method utilized during the 2008 event was only able to provide a qualitative evaluation of whether or not asbestos was present in the sample. In order to conduct a quantitative evaluation of the asbestos concentrations in surface soil, and to further define how far the asbestos impacts extend from the buildings, ARCADIS collected additional samples from the site in 2009. These surface soil samples were collected at

Igniter Assembly Area

representative locations where asbestos was detected during the 2008 sampling event. The samples were collected at distances of 1 ft, 5 ft, 10 ft, 15 ft, and 20 ft distances from the building at each sample location. A total of 6 rows of samples were collected for this evaluation (IAA-SS044 through IAA-SS049) and a minimum of one row of samples was collected at each of the IAA building types with conductive flooring. Note that the suffixes A, B, C, D, and E were used to designate whether the sample was collected 1, 5, 10, 15, or 20 ft from the building, respectively (e.g., IAA-SS044A). The samples were analyzed for asbestos by TEM CARB Level B in sequence by distance from building until the reported concentration was below 0.2% by weight. Once a low-detect result was achieved for a sample row, samples collected at further distances in the row were not analyzed. The sample locations from the 2009 investigation are depicted in Figure 7-2 and the analytical results are summarized in Table 7-15. The laboratory analytical reports are presented in Appendix E. The analytical results from the delineation sampling indicated the following:

- Asbestos fibers were detected in all 12 of the analyzed samples. However, the detected concentrations were less than 0.1% asbestos by weight in 7 of the 12 samples. Only two samples (IAA-SS044A and IAA-SS045A) had reported asbestos concentrations above 0.2%. The asbestos concentrations in samples IAA-SS044A (collected 1-ft from Building 8102-3) and IAA-SS045A (collected 1 ft from Building 8102-7) were 2.2% and 2.4%, respectively. The sample collected 5 ft from Buildings 8102-3 and 8102-7 had a reported concentrations of 0.1% and <0.1%, respectively. This indicates that the higher asbestos concentrations were confined to the soil immediately adjacent to the buildings.

- Chrysotile was the only asbestos type detected in the analyzed soil samples.

7.4.9.2 Activity Based Sampling

In an effort to facilitate an evaluation of the risk of exposure to airborne asbestos fibers resulting from asbestos in soil, ARCADIS conducted an activity based sampling program at two of the IAA buildings where asbestos had historical been detected in soil (Buildings 8102-1 and 5). This sampling program, which utilized the USEPA recommended generic action scenario of raking, was performed in accordance with USEPA *SOP 2094: Activity-Based Air Sampling for Asbestos* (USEPA, 2007c) and *Framework for Investigating Asbestos-Contaminated Superfund Sites* (USEPA, 2008g). The following subsections discuss the sample locations and analytical results.

7.4.9.2.1 Sample Locations

Building 8102-1 and Building 5 were selected for the 2009 activity based sampling programs based on the presence of asbestos detections during the 2008 sampling event and visible evidence of conductive flooring material having washed off the building pads onto surrounding soils. The following sample locations were established at each building:

- Two 10 ft by 10 ft sample grids were set up on the northeast side of Building 8102-1 in an area that has had historic asbestos detections. The first grid was located 0-10 ft from the edge of the building pad. The second grid was located adjacent to the first, but at a distance of 10-20 ft from the edge of the building. The grid locations are depicted in Figure 7-2.

- Two 10 ft by 10 ft sample grids were also established at the northeast side of Building 5. Like at Building 8102-1, the first grid was located 0-10 ft from the edge of the building and the second grid was located 10-20 ft from the building. The grid locations are depicted in Figure 7-2.

- Soil samples were collected from the centerline of each sampling grid pair at both buildings. The samples were collected at distances of 1, 5, 10, 15, and 20 feet from Building 8102-1 (IAA8102-SS001A through IAA8102-SS001E) and Building 5 (IAA5-SS001A through IAA5-SS001E). These samples were collected from a depth of 0-3 inches. The samples were analyzed for soil moisture by ASTM Method D2216-05, grain size by ASTM Method D6913-04e, and asbestos by TEM CARB Level B) to establish soil conditions and asbestos levels in the soil within the grids. The analytical results for the soil samples are presented in Table 7-15. The laboratory analytical reports are presented in Appendix E.

7.4.9.2.2 Activity Based Sampling Technique

This section presents a brief discussion of the sampling technique for the activity based sampling activities.

- Starting at the grid located furthest from Building 8102-1, each 10ft by 10 ft grid was vigorously raked by a participant wearing Level C person protection equipment to simulate an aggressive soil disturbance activity. During the raking activity, the participant wore a personal air monitoring pump fitted with a 0.8 µm MCE filter and sampling tube mounted in the subjects breathing zone.

A stationary air monitoring pump fitted with a 0.8 µm filter and sampling tube mounted at a height of 5 feet was also set on the downwind perimeter of the grid to collect air samples during the raking activity. The raking activity was performed for a duration that allowed a minimum of 750 to 1,000 liters of air to be pulled through each filter (approximately 2 hours).

- The personal air monitoring pump samples collected at each grid were identified as follows:
    - Building 8102-1, 0-10 ft Grid: IAA8102-AA1
    - Building 8102-1, 10-20 ft Grid: IAA8102-AA2
    - Building 5, 0-10 ft Grid: IAA5-AA1
    - Building 5, 10-20 ft Grid: IAA5-AA2

- The stationary perimeter air monitoring pump samples collected at each grid were identified as follows:
    - Building 8102-1, 0-10 ft Grid: IAA8102-AP1
    - Building 8102-1, 10-20 ft Grid: IAA8102-AP2
    - Building 5, 0-10 ft Grid: IAA5-AP1
    - Building 5, 10-20 ft Grid: IAA5-AP2

- In addition to the air samples collected at the sample grids, background air samples were collected near Building 8102-1 and 5 to evaluate the potential for background interferences. Stationary air monitoring pumps were set up at upwind locations at both buildings in a fashion similar to the stationary air monitoring pumps at the sampling grids. The background samples at Buildings 8102-1 and 5 were labeled IAA8102-BK2 and IAA5-BK2, respectively.

- All of the personal air monitoring pump samples, stationary perimeter pump samples, and background samples were submitted for laboratory analysis of asbestos by TEM Method 10312. The analytical results for all of the air samples are presented in Table 6-14. The laboratory analytical reports are presented in Appendix D. The analytical results from the TEM Method 10312 report the asbestos concentrations in air using several different methods, including: 1) the AHERA counting method; 2) PCME; and 3) total structures by TEM.

7.4.9.2.3 Laboratory Analytical Results

This subsection presents a summary of the analytical results from the 2009 activity based sampling areas:

Building 8102-1 Soil Samples: Asbestos concentrations in soil ranged from 17.2% asbestos by weight at 1 ft from the edge of the building to 0.1% asbestos or less in the samples collected 5, 10, 15, and 20 ft from the Building 8102-1. Chrysotile was the only type of asbestos fiber present in the samples. It should be noted that abundant red staining from the degraded flooring material was observed in the sample collected from the 1-ft interval.

Building 8102-1 Personal Air Monitoring Pump Samples: No asbestos fibers were detected in the personal air monitoring pump sample collected in the grid located 10-20 ft from the edge of Building 8102-1 (IAA8102-AA2). However, asbestos was detected in the personal air monitoring pump sample collected from the grid located 0-10 ft from Building 8102-1 (IAA8102-AA1). The results from this sample indicated that all of the detected fibers were chrysotile. The total asbestos concentrations in air reported via the various counting methods ranged from 0.00098 s/cc using PCME to 0.00783 s/cc using TEM.

Building 8102-1 Perimeter Air Monitoring Pump Samples: No asbestos fibers were detected in the perimeter air monitoring pump sample collected from the grid located 10-20 ft from the edge of Building 8102-1 (IAA8102-AP2). Asbestos was detected in the perimeter air monitoring pump sample collected 0-10 ft from Building 8102-1 (IAA8102-AP1). The results from this sample indicated that while the majority of the detected asbestos was chrysotile, single fibers of tremolite and amphibole asbestos were also detected in air. The total asbestos concentrations in air reported via the various counting methods ranged from 0 s/cc using PCME to 0.0534 s/cc using TEM.

Building 8102-1 Background Air Monitoring Pump Sample: No asbestos fibers were detected in the background air monitoring sample from Building 8102-1 (BKG8102-BK2).

Building 5 Soil: Chrysotile asbestos fibers were detected in each of the soil samples collected from grid centerline locations at Building 5. However, the reported concentrations of asbestos by weight in these samples were all less than 0.1%.

Building 5 Personal Air Monitoring Pump Samples: No asbestos fibers were detected in either of the personal air monitoring pump samples collected from the two sample grids located at Building 5 (IAA5-AA1 and IAA5-AA2).

Building 5 Perimeter Air Monitoring Pump Samples: No asbestos fibers were detected in either of the perimeter air monitoring pump samples collected from the two sample grids located at Building 5 (IAA5-AP1 and IAA5-AP2).

Building 5 Background Air Monitoring Pump Sample: No asbestos fibers were detected in the background air monitoring sample from Building 5 (IAA5-BK2).

7.5 Nature and Extent of Constituent Detections

The analytical results presented in the previous sections indicate that constituents have been detected at concentrations above applicable screening criteria at the IAA. The majority of the detections appear to be the result of degrading conductive flooring material in site buildings. Areas that have been investigated at the IAA include: soil surrounding all buildings that contain conductive flooring, soil surrounding the locations of former transformers, sediment from drainage ditches in the vicinity of buildings that contain conductive flooring, ponded water from within a subsurface concrete vault adjacent to Building 522, and building materials, including conductive flooring and paint samples.

7.5.1 Soil

7.5.1.1 Building Area Assessment

The primary focus of the environmental investigations at the IAA was to identify potential adverse affects to soil quality as a result of historical operations at the site or from degrading flooring material in site buildings. To this affect, approximately 98 surface soil samples and 50 subsurface soil samples were collected around the various IAA buildings between 1997 and 2008. An additional 475 surface soil sample were collected around the IAA buildings in 2008 for lead field screening using XRF. During 2009 approximately 22 additional surface soil samples and 10 air filter samples were collected for an activity based sampling effort designed to evaluate potential risks associated with asbestos in surface soil. Site maps depicting constituents detected above applicable RSLs in soil samples during the IAA investigation are presented in Figures 7-7 through 7-9. A site map depicting the results of the 2009 asbestos investigation is presented in Figure 7-10. Figures 7-3A and 7-3B display the results of the XRF field screening activities.

As illustrated by the figures, the results of the investigation activities indicated the following:

- No herbicides, or pesticides were detected in surface soil or subsurface soil samples at concentrations above residential RSLs.

- The explosive compound 2,4-dinitrotoluene (DNT) was detected at concentrations above the soil RSL in two samples from a single boring location near Building 504 during the 1997 site investigation. This constituent was not detected during any of the subsequent investigations, including samples collected near the location of the original 1997 detection.

Aroclor 1254 and Aroclor 1260 were the only PCBs detected in soil at the site. A limited number of the PCB detections were above applicable RSLs.

- o Aroclor 1254 was detected at 2002 sample location IASS05 (12/mg/kg) next to Building 8101. This concentration was above the industrial RSL for Aroclor 1254 of 0.74 mg/kg. Aroclor 1254 was not detected above the residential RSL in two surface soil samples (IAA-SS01 and IAA-SS002) and one subsurface soil sample (IAA-SB001) that were collected next to Building 8101 in 2008; therefore, the detection at IASS005 is believed to be isolated.

- o Aroclor 1254 was also detected at concentrations above the residential RSL in surface soil samples collected adjacent to Building 502 [50240 (0-1 ft bgs] and Building 504 [504312 (0-1 ft bgs), 504336 (0-1 ft bgs) and 504360(0-1 ft bgs)] during the 1997 investigation. Aroclor 1254 was also detected above the industrial RSL in one subsurface soil sample [504360 mg/kg (1-2 ft bgs)] next to Building 504. No other surface soil or subsurface soil samples in this area contained PCBs at concentrations above applicable residential RSLs.

- o Aroclor 1260 was detected in one surface soil sample (SS-11) next to Building 8102-5 at a concentration above the industrial RSL; and in one surface soil sample next to Building 8102-A at a concentration above the residential RSL during the 1997 investigation. Aroclor 1260 was not detected in any other samples around IAA buildings.

- Several SVOC/PAH compounds were detected in isolated surface soil samples at concentrations above applicable RSLs, including: bis(2-ethylhexyl)phthalate, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene.

- Several inorganics were detected in soil samples collected around the IAA buildings at concentrations above applicable RSLs. In most cases the concentrations above the applicable RSLs were detected in surface soil samples collected immediately adjacent to buildings with conductive flooring material. Inorganics concentrations typically decreased considerably with depth and distance from the buildings. Inorganics that were detected above RSLs included:

  - **Aluminum** – Aluminum was detected at concentrations above the residential RSL and slightly above the established background level (40,041 mg/kg) in two subsurface soil samples [81027160 (1-2 ft bgs) and IASB13 (2-4 ft bgs)]. Aluminum was not detected at concentrations above background in any other surface soil or subsurface soil samples at the IAA.

  - **Arsenic –** Arsenic was detected above the background level and industrial RSL in 16 surface soil samples and 1 subsurface soil sample. The detected concentrations in these samples were typically only slightly above the established background level of 15.8 mg/kg. The maximum detected arsenic concentration (164 mg/kg) occurred in 1998 sample SS-12 next to Building 8102-6. During a later 1998 investigation, soil boring IASB4 was advanced at the SS-12 sample location. The results from surface soil and subsurface soil samples indicated that arsenic concentrations were below background.

  - **Barium** - Barium was detected above the residential RSL and established background level in nine surface soil samples. Three of the samples with detections above the residential RSL were collected adjacent to Building 8102-5 (SS-11, SS-11A, and SS-11b). The maximum detected barium concentration of 11,800 mg/kg at sample location SS-11A was also collected adjacent to Building 8102-5. The other samples that had barium concentrations above residential RSLs were collected with 1-3 ft of buildings with conductive flooring. Barium was not detected above RSLs in any subsurface soil samples.

- **Cadmium** – Cadmium was detected above background levels and the residential RSL in three surface soil samples collected within 1-ft of IAA buildings. Soil samples SS-011 (7.8 mg/kg) and IAA-SS015 (15.2 mg/kg) were collected adjacent to Building 8102-5, and soil sample IAA-SS033 (9.20 mg/kg) was collected adjacent to Building 522A. Cadmium was not detected above the industrial RSL in any samples

- **Chromium** – Chromium was detected above the residential RSL in 5 surface soil samples and above the industrial RSL in one subsurface soil sample [504360(1-2 ft bgs)]. All of the samples with chromium concentrations above applicable RSLs were collected in the vicinity of Buildings 502 and 504. The chromium concentrations in this area were above the residential RSL in samples collected up to 10-ft from the buildings.

- **Cobalt** – Cobalt was detected above the industrial RSL and above established background levels in three surface soil samples SS-11, SS-12, and IASB07 in the central portion of the IAA. No other surface soil samples or subsurface soil samples contained cobalt at concentrations above background.

- **Copper** – Copper, which is thought to have been a major component of the conductive flooring material, was the inorganic most frequently detected at concentrations above applicable RSLs.

    - Copper was detected above the residential RSL (310 mg/kg) in 34 surface soil samples and one subsurface soil sample collected during the course of investigation. The one subsurface soil sample that had a concentration above the residential RSL [504360 (1-2 ft bgs)] was collected from approx 1 to 2 ft bgs near Building 504. Copper was not detected above background levels in deeper samples collected in this area or any other area of the IAA.

Igniter Assembly Area

- § The detected copper concentrations in 12 surface soil samples were above the industrial RSL of 4,100 mg/kg. The samples with concentrations above industrial RSLs were all collected within 1 to 3 ft of buildings with conductive flooring material.

- § The highest detected concentration of copper (56,500 mg/kg) occurred at sample location SS-12, next to Building 8102-6 during a 1998 sampling event. Soil boring IASB4 was advanced at the SS-12 location later in 1998. The surface soil sample from IASB4 resulted in a copper concentration slightly above background, but below the residential RSL and the subsurface soil sample (collected from 5-6 ft bgs) had a copper concentration below the background level. Copper concentrations were also below residential RSLs in surface soil samples collected in this area during the 2002 investigation (IASS01 and IASS03).

- § The most widespread copper detections were found in soil samples collected around Buildings 502, 504, 522, and 522A in the southern portion of the IAA. Copper was detected above the residential RSL in 8 of the 34 soil samples collected in this area and included one sample (IAA-SS029) collected 10-ft from Building 502. The results of the XRF analysis indicated that this area also contained the most widespread lead concentrations above applicable RSLs.

o **Lead** – Lead is also believed to have been a major component of the conductive flooring material, and was the inorganic second most frequently detected at concentrations above applicable RSLs.

- § Lead was detected at concentrations above the residential RSL in 20 surface soil samples and 2 subsurface soil samples. Of these detections, 14 surface soil samples and both subsurface soil samples were also above the industrial RSL of 800 mg/kg. The maximum detected lead concentration (16,200 mg/kg) was detected at sample location 504360, which was collected near Building 504.

Igniter Assembly Area

- § Nine of the surface soil samples with concentrations above industrial RSLs were collected near Buildings 502, 504, 522, and 522A in the southern portion of the IAA (504312, 504336, 504360, IASB14, IAA-SS026, IAA-SS028, IAA-SS0029, IAA-SS032, and IAA-SS033). Two of the samples with concentrations above the residential RSL were also collected next to Building 504 (IASB15 and IAA-SS027). These samples were collected at distances up to 10-ft from the buildings in this area. The results of the XRF sampling also indicated that lead concentrations were highest in this area of the site.

- § The two subsurface soil samples with concentrations above the industrial RSL [504336 (1-2 ft bgs) and 504360 (1-2 ft bgs)] were collected adjacent to Building 504 at a depth of 1-2 ft bgs. Additional sampling conducted in this area indicated that lead concentrations in deeper soils were below residential RSLs. Lead was not detected above applicable RSLs in any other subsurface soil samples collected at the IAA.

- § Eleven surface soils collected from the central portion of the IAA also had lead concentrations above applicable RSLs. In general these samples were collected from distances of less than 5-ft from the main igniter assembly buildings. The XRF sampling from this area confirmed that the lead concentrations around these buildings were generally below residential RSLs.

- o **Iron** – Iron was detected above the residential RSL and background levels in five surface soil samples and three subsurface soil samples. The maximum detected concentration was 328,000 mg/kg at sample location IAA-SS028, which was collected 5 ft from Building 502.

- o **Mercury** – Mercury was detected in two surface soil samples at concentrations above industrial RSLs. Mercury was detected at a concentration of 3.30 mg/kg at 1997 sample location 502460 (0-1 ft bgs) next to Building 502. It was also detected at a concentration of 79.5 mg/kg in 2008 sample location IAA-SS022 next to Building 8102-

8. Mercury was not detected above residential RSLs in any other surface or subsurface soil samples at the IAA.

- **Nickel** – The nickel concentrations detected at the IAA were typically below the established background concentration of 62.8 mg/kg. However, the concentration in one surface soil sample collected adjacent to Building 504 [IAA-SS028 (213 mg/kg)] was above background and the residential RSL. Several other inorganics (arsenic, chromium, copper, iron, lead) were also detected at concentrations above screening levels at this location.

- **Zinc** – Zinc was detected above the established background level of 202 mg/kg in 38 surface soil samples and 2 subsurface soil samples. However, the detected concentrations were only higher than the residential RSL in 9 surface soil samples and 1 subsurface soil sample. Zinc was not detected above the industrial RSL in any surface or subsurface soil samples. The samples with elevated zinc concentrations typically occurred with 1 to 5 ft of buildings.

During the 2008 investigation, asbestos was detected in 20 of the 41 surface soil samples collected within 1-10 ft of the IAA buildings with conductive flooring. However, during the 2009 investigation it was demonstrated that while chrysotile asbestos fibers are present in the surface soil around IAA buildings, the concentrations are generally very low (i.e., 0.1% by weight or less). Only three samples during the 2009 investigation contained asbestos at a concentration above 1%. These samples, IAA8102-SS001 (17.2% asbestos by weight), IAA-SS044A (2.2% by weight), and IAA-SS045A (2.4% by weight) were all collected within 1 ft of IAA buildings where degraded conductive flooring material had washed off site buildings. Samples collected 5 ft away from the buildings at these locations all had asbestos concentrations of 0.1% by weight or less, which confirms that the asbestos impacts are largely confined to the surface soils located immediately adjacent to the buildings. Visual observation of the degraded flooring material that has washed off the building pads further indicates that it is generally confined to the soil immediately adjacent to the buildings.

While asbestos in soil is not inherently hazardous, the activity based sampling event conducted at the IAA demonstrated that intensive soil disturbance activities in areas located immediately adjacent to the buildings (i.e., areas where high concentrations of asbestos may be present in soil) has the potential to result in measureable concentrations of asbestos in air. TEM analysis conducted on personal air monitoring

Igniter Assembly Area

pump and perimeter air monitoring pump filter samples associated with activity based sampling in a grid located within 0-10 ft of IAA Building 8102-1 (where asbestos was detected in soil at a concentration of 17.2% by weight 1-ft from the building) indicated asbestos concentrations in air of 0.00783 s/cc and 0.0534 s/cc, respectively. Activity based sampling conducted in a grid located 10-20 ft from Building 8102-1, where asbestos concentrations in soil were below 0.1% by weight did not generate any measureable asbestos concentration in air. Similarly, activity based sampling at Building 5 at the IAA, where asbestos concentrations in soil were below 0.1% by weight, did not generate any airborne asbestos fibers.

In summary, the environmental investigations at the IAA have confirmed that soils surrounding several of the buildings have been affected by asbestos and the leaching of inorganics from the deteriorating conductive flooring material. Inorganics, primarily lead, arsenic, chromium, copper, and zinc have been detected at concentrations above applicable RSLs. The elevated inorganics concentrations are typically confined to soils in the immediate vicinity of the buildings (i.e., less than 5-ft distance from building footprint) with the exception of the area around Buildings 502, 504, 522, and 522A, where the elevated inorganics concentrations extend up to 15-ft from the buildings in some locations. Subsurface sampling has confirmed that the elevated concentrations are confined to surface soil, as no samples deeper than 2-ft bgs contained inorganics at concentrations above background levels and residential RSLs. Elevated asbestos concentrations are also confined to surface soils located immediately adjacent to the buildings with conductive flooring. The PCBs and PAH compounds that were detected above applicable RSLs have been delineated and are isolated to very small areas.

7.5.1.2 Former Transformer Area Assessment

Eight samples were collected from locations of former pole mounted transformers in 2002 (IATR01 through IATR08). With the exception of the transformer at the IATR04 sample location, the transformers are no longer present at the site and little to no physical evidence (i.e., pole stumps, staining, or stressed vegetation) of the transformer locations remain. Therefore, the sample locations, depicted in Figure 7-2, were selected based on a base utility drawing dated April 1942. The analytical results for the transformer area samples are presented in Table 7-12. The analytical results indicated that the PCB Aroclor 1260 was detected at a concentration of 0.40 mg/kg at sample location IATR07. This concentration is slightly higher than the residential RSL for Aroclor 1260 of 0.24 mg/kg. No other PCBs were detected at any of the other transformer area sample locations. A site map depicting the sample results at the transformer sample locations is presented in Figure 7-7 through Figure 7-9.

7.5.2 Sediment

There are no surface water bodies or aquatic habitats in the immediate vicinity of the IAA. However, there are several drainage ditches located within the boundaries, and on the perimeter, of the IAA. During the course of environmental investigation at the IAA, samples have been collected from the drainage pathways to evaluate the potential for runoff from the buildings and other areas of the site to have transported constituents into the ditches. The samples collected from the drainage ditches have been called sediment samples due to the loose nature of some of the material, but would be more accurately classified as surface soil. The drainage ditches were all dry at the time of sampling.

Two samples (IASD11 and IASD12) were collected during a 2002 site investigation from the storm water drainage swales that capture runoff from around the main igniter assembly buildings. These swales were designed to capture runoff from the central portion of the IAA that does not infiltrate into the flat grassy areas between the buildings; therefore, the swales would be a likely depositional point for any constituents of concern transported from the buildings by rain water runoff. These sample were analyzed for a full suite of analytes, including explosives, pesticides, PAHs, PCBs, VOCs, SVOCs, and inorganics. The analytical results from these samples indicated that no explosives, pesticides, herbicides, PCBs, or VOCs were detected at concentrations above applicable residential RSLs. Several PAHs were detected in both samples; however, only benzo(a)pyrene was detected in both samples at concentrations above residential RSLs. Inorganics analysis indicated that lead and zinc were detected at concentrations above applicable background levels in IASD12, but that only lead (643 mg/kg) was present at concentrations above the residential RSL. Lead was also detected at a concentration slightly above background in IASD11, but below the residential RSL.

During the 2008 site investigation, samples were collected from the drainage ditch downgradient of the IASD12 sample location. The samples were field screened for lead using XRF (IAA-SE001X through IAA-SE006X). Two samples (IAA-SE003 and IAA-SE004) were also submitted for laboratory analysis of TAL metals. The results of both the field screening and laboratory analysis indicated that lead was present at concentrations slightly above background, but below residential RSLs. No other inorganics were detected at concentrations above background levels.

Seven sediment samples (IASD4 through IASD10) were also collected during the 2002 site investigation from drainage pathways or culverts that control surface water runoff

Igniter Assembly Area

in the vicinity of the expanded IAA. These samples were spaced around the perimeter of the IAA, further away from the assembly buildings than IASD11 and IASD12. The samples were analyzed for a full suite of analytes, including explosives, pesticides, PCBs, VOCs, SVOCs, and TAL metals. The analytical results indicated the following:

- No explosives, pesticides, PCBs, or VOCs were detected at concentrations above applicable residential RSLs.

- Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were detected at concentrations above the industrial RSL at sample location IASD09. This sample was collected from a drainage culvert that passes under Cameron Road in the southern portion of the IAA.

- Benzo(a)pyrene was detected at a concentration above the industrial RSL at sample location IASD10. Benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were also detected at concentrations above the residential RSL at IASD10. This sample location was also collected from a drainage culvert that passes under Cameron Road in the southern portion of the IAA.

- Benzo(a)pyrene was also detected at concentrations above the residential RSL at samples IASD05, and IASD06.

- Lead was detected at a concentration above the industrial RSL at sample location IASD06 (884 mg/kg). No other inorganics were detected at concentrations above applicable RSL and background levels.

During the 2008 site investigation, samples were collected from the drainage ditch downgradient of the IASD6 sample location. The samples were field screened for lead using XRF (IAA-SE007X through IAA-SE009X). Two samples (IAA-SE001 and IAA-SE002) were also submitted for laboratory analysis of TAL inorganics. The results of both the field screening and laboratory analysis indicated that lead was present at concentrations slightly above background, but below residential RSLs. No other inorganics were detected at concentrations above background levels.

A site map depicting the analytical results from the sediment sampling activities is presented in Figure 7-11.

7.5.3 Surface Water

There are no surface water bodies (i.e. streams or ponds) in the vicinity of the IAA, and the area drainage ditches only carry surface water runoff during very heavy rainfall events; therefore, no true surface water samples were collected during the investigation of the IAA. However, one water sample (IAA-VTLW01) was collected at the IAA from ponded water within a subsurface concrete vault located below a sidewalk adjacent to Building 522. The sample location is depicted in Figure 7-11. Sample IAA-VTLW01 was submitted for laboratory analysis of VOCs, SVOCs/PAHs, and TAL inorganics. Acetone was detected at an estimated concentration of 0.0051 mg/L which is below the tap water RSL of 22 mg/L. No other VOCs and no SVOCs (PAHs) were detected in the sample. Inorganics detected in the sample were all at concentrations below respective tap water RSLs.

7.5.4 Conductive Flooring and Building Materials

Conductive flooring material is present on 27 of the 35 building pads at the IAA. Results of the conductive flooring survey indicate that there is approximately 25,000 ft^2 of conductive flooring present on building pads at the IAA. The condition of the flooring during the 2008 investigation ranged from mostly intact to highly deteriorated. Based on the flooring characterization sampling events, the flooring is known contain aluminum, arsenic, barium, chromium, copper, iron, lead, and zinc; as well as several other inorganics that have been identified in soils at the IAA. The flooring material is also known to contain asbestos.

While very little paint remains on the concrete walls of the IAA buildings, the two paint chip samples collected in 2005 and analyzed for lead did indicate that the paint contained lead. The reported lead concentrations in both of the samples (e.g., IAPC02 [37,200 mg/kg) and IAPC03 [49,500 mg/kg]) were greater than 0.5% by weight (i.e., 5,000 mg/kg) which is the minimum concentration that the federal government uses to define lead based paint in residences (40 CFR 745.223).

7.6 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. Risk assessment datasets for soil, sediment, and surface water for the IAA were prepared then summarized and statistically analyzed per methods described in Appendix A. Risk assessment datasets summaries highlighting the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPC are presented in Tables 7-17 through Table 7-20.

7.7 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with constituents detected in soil and sediment samples collected at the IAA. No surface water samples were collected at the IAA; as a result, this medium was not evaluated. The general risk assessment approach follows the Radford Army Ammunition Plant Final Master Work Plan (URS 2003) as presented in Appendix A. The approach for evaluating the risks associated with asbestos in soil is somewhat different than the other constituents at the site. The approach for evaluating asbestos is presented in detail in Section 4.4.5 of Appendix A.

7.7.1 Selection of Constituents of Potential Concern

This section discusses the selection of COPCs for the HHRA for each medium at the IAA.

7.7.1.1 Surface Soil

Surface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 7-21 presents the selection of surface COPCs for the HHRA. As summarized in Table 7-21, 27 constituents were identified as COPCs in surface soil:

- **VOCs:** 3-octanone and d-limonene;
- **SVOCs:** carbazole, 2,4-dinitrotoluene, and bis(2-ethylhexyl)phthalate
- **PAHs:** benzo[a]anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene;
- **PCBs:** Aroclor 1254 and Aroclor 1260; and
- **Inorganics:** aluminum, antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, mercury, nickel, and zinc.

In addition to the constituents listed above, asbestos has been identified as a COPC for surface soil at the IAA. Soil sampling conducted at the site has confirmed the presence of asbestos in soil immediately adjacent to site buildings where conductive flooring has washed off the building pads. While asbestos fibers in soil are not inherently hazardous, activity based sampling has indicated that intensive soil disturbance activities in the areas located immediately adjacent to the buildings, where soil asbestos concentrations are highest, have the potential to generate measureable concentrations of asbestos in air.

7.7.1.2 Combined Surface and Subsurface Soil

Combined surface and subsurface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 7-22 presents the selection of combined surface and subsurface soil COPCs for the HHRA. As summarized in Table 7-22, 27 constituents were identified as COPCs in combined surface and subsurface soil:

- **VOCs:** 3-octanone and d-limonene;
- **SVOCs:** carbazole, 2,4-dinitrotoluene, and bis(2-ethylhexyl)phthalate;
- **PAHs:** benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene;
- **PCBs:** Aroclor 1254 and Aroclor 1260; and
- **Inorganics:** aluminum, antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, mercury, and nickel.

7.7.1.3 Sediment

Sediment COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 7-23 presents the selection of sediment COPCs for the HHRA. As summarized in Table 7-23, six constituents were identified as COPCs in sediment: aluminum, arsenic, cobalt, iron, manganese, and vanadium.

7.7.2 Human Health Risk Characterization

Although not currently occupied, under current land use conditions, site workers were identified as a potential receptor due to the industrial use of the IAA and surrounding area. Assuming hypothetical redevelopment of the area for residential land use, construction workers, adult and child residents were identified as potential receptors.

Exposure to COPCs in soil and sediment were evaluated for direct contact. VOCs identified as COPCs in the IAA were also evaluated for inhalation via vapor migration into buildings. Two VOCs, 3-octanone and d-limonene, were identified as soil COPCs at the IAA. Those two COPCs do not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area. In addition, potential risks associated with inhalation of asbestos becoming airborne from soil were estimated. These are summarized in Section 7.7.3. Uncertainties associated with potential risk from exposure to 3-octanone and d-limonene were discussed in Appendix A. The EPCs for the IAA are provided in Table 7-24.

The ELCRs and non-cancer hazards and the estimated blood lead levels for each potentially exposed receptor included in the risk assessment for the IAA are presented in Appendix A and are summarized in Tables 7-25 and 7-26, respectively. These results are presented in the tables below and are discussed by receptor in following subsections.

Summary of Calculated ELCRs and HIs for Receptor Exposure Scenarios

RECEPTOR/ EXPOSURE MEDIUM – SCENARIO	ELCR	HI
Site Worker		
Surface Soil - Direct Contact	1E-04	1
Sediment – Wading	8E-07	0.01
TOTAL SITE RISKS (Site Worker):	**1E-04**	**1**
Hypothetical Future Construction Worker		
Combined Surface and Subsurface Soil - Direct Contact	6E-06	3
TOTAL SITE RISKS (Construction Worker):	**6E-06**	**3**
Hypothetical Future Adult Resident		
Combined Surface and Subsurface Soil - Direct Contact	**-**	1
Sediment – Wading	-	0.02
TOTAL SITE RISKS (Adult Resident):	-	**1**

Summary of Calculated ELCRs and HIs for Receptor Exposure Scenarios (continued)

RECEPTOR/ EXPOSURE MEDIUM – SCENARIO	ELCR	HI
Hypothetical Future Child Resident		
Combined Surface and Subsurface Soil - Direct Contact	-	13
Sediment – Wading	-	0.1
TOTAL SITE RISKS (Child Resident):	**-**	**13**
Hypothetical Future Resident (Adult and Child)		
Combined Surface and Subsurface Soil - Direct Contact	5E-04	-
Sediment – Wading	3E-06	-
TOTAL SITE RISKS (Resident):	**5E-04**	**-**

Summary of Estimated Blood Lead Levels for Receptor Exposure Scenarios.

RECEPTOR	**Estimated Blood Lead Level (µg/dL)**		
	Adult	**Child**	**Fetus**
	50th percentile	**Range**	**95th percentile**
Site Worker	2.8	–	10
Hypothetical Future Construction Worker	2.8	–	10
Hypothetical Future Child Resident	–	4.4 – 8.2	–
Hypothetical Future Adult Resident	3.2	–	11

*See Appendix A for individual tables.

7.7.2.1 Site Worker

A current or future site worker could be present at the IAA area, and could be exposed to surface soil or sediment. The ELCR and non-cancer hazard index for site worker exposure to each medium are presented in Appendix A, and are summarized in Table 7-25. As presented in the table above, the ELCRs for surface soil and sediment are all below or equal to the high end of the USEPA target risk range, and the HIs for each medium are all below or equal to the benchmark value of 1.

The total cumulative ELCR for site workers exposed to surface soil and sediment at the IAA is 1×10^{-4}, which is at the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 1, which is at the benchmark of 1. The 50th percentile blood lead level estimates for the site worker receptor was at 2.8

µg/dL which is well below the benchmark of 10 µg/dL. The 95th percentile fetal blood lead levels (9.9 µg/dL) was equivalent to the benchmark of 10 µg/dL.

7.7.2.2 Hypothetical Future Construction Worker

A hypothetical future construction worker could be present at the IAA area, and could be exposed to combined surface and subsurface soil. The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the IAA was 6×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 3, which is above the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were all below or equal to the benchmark of 1. The 50th percentile blood lead level estimates for the construction worker receptor was at 2.8 µg/dL which is well below the benchmark of 10 µg/dL. The 95th percentile fetal blood lead levels estimated (9.9 µg/dL) was equivalent to the benchmark of 10 µg/dL.

7.7.2.3 Hypothetical Future Residents

A hypothetical future resident could be present at the IAA area, and could be exposed to combined surface and subsurface soil and sediment. The ELCR and non-cancer hazard index for hypothetical future adult and child resident exposure to each medium are presented in Appendix A and are summarized in Table 7-25.

The ELCR for sediment is within the USEPA target risk range; however, the ELCR for combined surface and subsurface soil is greater than the USEPA risk range. The HIs for each medium are all at or below the benchmark value of 1, with the exception of child resident exposure to combined surface and subsurface soil.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil and sediment at the IAA is 5×10^{-4}, which is slightly above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}.The primary risk driver is 2,4-dinitrotoluene in soil. Other contributors to the excess lifetime cancer risks were benzo(a)pyrene, Aroclor 1254, and arsenic.

The total cumulative HI for hypothetical future adult residents is 1, which is equal to the benchmark. When the hazards were segregated by target organ or critical effect, all of the HIs were less than 1. The total cumulative HI for hypothetical future child residents is 13, which is above the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were greater than the benchmark of 1 in the central nervous system, whole body, and immune system, in the blood, in the gastrointestinal tract, and in the eyes, nails, hair, and skin. The risk drivers for non-cancer hazard are Aroclor 1254, copper, 2,4-dinitrotoluene, and cobalt.

The 50th percentile blood lead level estimates for the hypothetical adult resident receptor was calculated to be 3.2 µg/dL which is well below the benchmark of 10 µg/dL, and the 95th percentile fetal blood lead levels was calculated to be 11 µg/dL slightly above the benchmark of 10 µg/dL, as seen in Table 7-26. The range of annual mean blood lead level estimates over seven years for the child receptor was 4.4µg/dL to 8.2 µg/dL, which is below the benchmark of10 µg/dL. However, exposure of a child over a seven year period resulted in a geometric mean blood lead concentration of 6.4 µg/dL, below the 10 µg/dL benchmark, but a prediction of 17 percent of the population having blood lead concentrations above the 10 µg/dL benchmark.

7.7.3 Asbestos Evaluation

As discussed in Appendix A, the risks and hazards associated with asbestos in soil cannot be evaluated utilizing traditional risk assessment techniques. This is because the measurement of asbestos in soils may not be a good indicator of potential for exposure due to the fact that the main route of asbestos toxicity is through inhalation of fibers. Thus, the important metric in defining potential risk is the measurement of asbestos fibers in air within a breathable zone. Based on this information, USEPA recommends that the results of activity-based air sampling be utilized to determine whether disturbance of soils in areas known to contain asbestos can result in the mobilization of asbestos into air at potential hazardous levels where it may be inhaled by the individuals engaged in activities there.

To evaluate the results of the activity based sampling conducted at the IAA in 2009, AALs have been developed for relevant, site-specific, exposure scenarios in accordance with the methods outlined in the USEPA's Framework for Investigating Asbestos-Contaminated Superfund Sites (2008f). AALs were calculated for all of the exposure scenarios identified at the IAA including the current and future site worker, the hypothetical future construction worker, the hypothetical future adult resident, and the hypothetical future child resident. The AALs were calculated for each potential receptor group at the 1E-06 and 1E-04 risk levels, representing the lower and upper ends of USEPA's acceptable risk range. The calculation of the AALs is presented in detail within Section 4.4.5 of Appendix A. The calculated AALs are presented in the following table.

	Calculated AAL (s/cc) at Indicated Target Risk Level	
Receptor Group	Target Risk = 1E-06	Target Risk = 1E-04
Current/Future Site Worker	0.00007	0.007
Hypothetical Future Construction Worker	0.002	0.2
Hypothetical Future Child Resident	0.00002	0.002
Hypothetical Future Adult Resident	0.00001	0.001

The results of the activity based sampling conducted at IAA Building 5 indicated that no airborne asbestos fibers were detected for either of the two sampling grids at this building. The results of the activity based sampling event at IAA Building 8102-1 also indicated that no airborne asbestos fibers were detected in the sampling grid located 10-20 ft from the edge of the buildings, where asbestos concentrations in soil were <0.1%. However, airborne asbestos fibers were detected in both the personal air monitoring pump sample (IAA8102-AA1) and the perimeter air monitoring pump sample (IAA8102-AP1) collected from the activity based sampling grid located 0-10 ft from Building 8102-1 (asbestos had been detected in soil within the grid at a concentration of 17.2% by weight 1-ft from the edge of the building). The airborne concentrations were 0.00783 s/cc and 0.0534 s/cc for the personal air monitoring pump and perimeter air monitoring pump sample, respectively. The average concentration in air at Building 8102-1 was 0.015 s/cc using the two detections and two non-detect results. The detected concentrations in the two samples collected adjacent to Building 8102 and the overall average for Building 8102 exceed the AAL of 0.007 s/cc (based on a 1E-04 risk level) calculated for the current and future site worker, as well as the range of AALs calculated for hypothetical future residents. They do not exceed the AAL of 0.2 calculated for the hypothetical future construction worker.

These results indicate that the presence of high asbestos concentrations in soils adjacent to Building 8102, and other IAA buildings where conductive flooring may have contributed to elevated asbestos concentrations in soil, may result in unacceptable air concentrations if those soils are subject to intensive disturbance. These unacceptable risks would be expected under the current/future industrial scenario and hypothetical future residential exposure scenarios.

7.7.4 Human Health Risk Summary

Table 7-25 summarizes the calculated cancer risks and non-cancer hazards for each potential exposure scenario included in the risk assessment for the IAA. The total ELCR values for all surface soil, combined surface and subsurface soil and sediment exposures for each exposure scenario are below or within the benchmark range of 10^{-6} to 10^{-4} for cancer risk, with the exception of hypothetical future adult and child resident exposure to combined surface and subsurface soil. The primary risk driver is 2,4-dinitrotoluene. However, benzo(a)pyrene, Aroclor 1254, and arsenic also contributed to the elevated residential risks.

The total HI values for all surface soil, combined surface and subsurface soil, and sediment exposures for each exposure scenario are below or equal to the benchmark of 1 for non-cancer hazard, with the exception of hypothetical future construction worker and hypothetical future child resident exposure to combined surface and subsurface soil. When the HI is segregated into target site and critical effects for the hypothetical future construction worker, hazards were all below or equal to the benchmark of 1. The primary contributors to the hazards above 1 for the hypothetical future child resident are 2,4-dinitrotoluene, Aroclor 1254, copper, and cobalt.

The results of the risk assessment indicate that under industrial exposure scenarios the calculated excess lifetime cancer risks, noncancer hazards, and predicted blood lead levels were all within target risk ranges or less than or equal to benchmarks.

The results of the risk assessment for hypothetical future residential receptors indicated that 2,4-dinitrotoluene, Aroclor 1254, cobalt, and lead were COCs for both adult and child residents due to detections in soil. While 2,4-dinitrotolune was identified as a potential risk driver in soil for the residential scenario, it should be noted that this compound was detected in only two samples at the IAA. These samples were from the same location during the initial sampling event at the site, and no other detections occurred in subsequent events. Similarly, cobalt was only detected outside of the background range in one sample. As such, cobalt and 2,4-dinitrotoluene are not considered drivers for remediation at the site. Aroclor 1254 was detected in 18 of 61 surface soil samples with concentrations ranging from 0.03 to 12 mg/kg. Only three samples exceeded the industrial RSL of 0.74 mg/kg and six samples exceeded the residential RSL of 0.22 mg/kg.

As discussed in Section 7.5, removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and wash onto the surrounding soils. Activity based sampling conducted at the IAA has demonstrated that intensive disturbance of the soils located immediately adjacent to the buildings where the flooring has washed off the building pads has the potential to generate airborne asbestos concentrations that may present an unacceptable risk to human receptors under current and hypothetical future industrial and/or residential land use scenarios. Soil sampling at the IAA has indicated that the elevated concentrations of asbestos in soil that have the potential to generate the airborne asbestos concentrations are primarily located immediately adjacent to (i.e. within 1-ft) the site buildings, which is the same general area where the elevated inorganics concentrations are located.

While not evaluated in the risk assessment any residual lead based paint on the concrete walls at the IAA or other possible asbestos containing building materials (i.e., pipe insulation, joint compounds, mastic, etc.) could also present a risk for current and future site workers, construction workers, or residents.

7.8 Ecological Risk Assessment

The purpose of the ERA is to evaluate whether ecological receptors may be adversely impacted by exposure to site-related constituents detected in surface soil, sediment, and surface water at the IAA. This section summarizes the occurrence of constituents in each medium and identifies COPECs at the IAA for the ERA; identifies the potential ecological exposure scenarios relevant to the IAA; and presents the estimated ecological risks associated with the identified COPECs and the relevant ecological exposure scenarios at the IAA. Methodologies for data summary and selection of COPECs, exposure assessment, and toxicity assessment for the ERA are presented in Appendix A.

7.8.1 Selection of Constituents of Potential Ecological Concern

This section discusses the selection of COPECs for each medium. Risks to ecological receptors are calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the hazard quotient (HQ), is a conservative surrogate for the assessment endpoints identified in

Appendix A. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse ecological effects are unlikely (USEPA 1997c). HQs greater than 1 indicate that further evaluation is warranted. Therefore, the constituents with HQs greater than 1 or that are bioaccumulative are carried forward as COPECs into the BERA. Maximum HQs greater than 1 for the IAA are summarized in the subsections below.

7.8.1.1 Surface Soil

Surface soil COPECs were selected by comparing the analytical data with USEPA (2005b) EcoSSLs, USEPA (2003e) Region 5 ESLs, and ORNL values (Efroymson et al. 1997a,b) for surface soil. Table 7-27 presents the selection of surface soil COPECs for the ERA. As summarized in Table 7-27, 53 constituents were identified as COPECs in surface soil:

- **VOCs:** 3-octanone and d-limonene;
- **SVOCs:** 2,4-dinitrotoluene, benzoic acid, bis(2-ethylhexyl)phthalate, carbazole, dibenzofuran, diethylphthalate, and di-n-butylphthalate;
- **Explosives:** nitroglycerine;
- **Pesticides:** 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, beta-BHC, delta-BHC, alpha-chlordane, dieldrin, endosulfan II, endrin, heptachlor epoxide, and methoxyclor,
- **PAHs:** acenaphthene, acenaphthylene, anthracene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, naphthalene, phenanthrene, and pyrene
- **PCBs:** Aroclor 1254 and Aroclor 1260; and
- **Inorganics:** antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, mercury, nickel, selenium, silver, and zinc.

7.8.1.2 Sediment

Sediment COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2009a) Region 3 Sediment Screening Levels; ORNL values (Jones et al. 1997); and USEPA (2003e) Region 5 Ecological Screening Levels for sediment. Table 7-28 presents the selection of sediment COPECs for the ERA. The following constituents were selected as COPECs in sediment:

- **Inorganics:** arsenic, barium, beryllium, cadmium, chromium, copper, iron, lead, nickel, vanadium, and zinc

7.8.2 Summary of Selected Constituents of Potential Ecological Concern

Fifty-three constituents were selected as COPECs in surface soil and eleven constituents were selected as COPECs in sediment because the HQs were greater than 1, the chemical was bioaccumulative, or an HQ could not be calculated because an ESL was not available.

7.8.3 Refinement of Risk Calculations for Direct Contact COPECs

The list of COPECs identified in the BERA was reevaluated by calculating refined HQs. The refined HQs were calculated for the COPECs identified in the SLERA using refined EPCs. Constituents identified as COPECs in the BERA that were bioaccumulative were carried forward into food chain models. The results of the recalculation of the HQs for the BDDT are summarized in the subsections below.

7.8.3.1 Surface Soil

Fifty-three COPECs in surface soil were carried forward into the BERA. When refined EPCs were compared with the ESLs, 15 constituents [2,4-dinitrotoluene, bis(2-ethylhexyl)phthalate, diethylphthalate, di-n-butylphthalate, benzo(a)pyrene, naphthalene, antimony, barium, cadmium, chromium, cobalt, copper, lead, mercury, and zinc] had a refined HQ greater than 1. In addition, ESLs were not available for 9 other constituents (3-octanone, d-limonene, benzoic acid, carbazole, dibenzofuran, nitroglycerine, Aroclor 1254, Aroclor 1260, , and iron). The BERA results for surface soil COPECs at the IAA are presented in Table 7-29 and are discussed in Appendix A. The results of the refined analysis indicate that adverse effects to wildlife due to potential COPEC exposure are considered unlikely.

Of the COPECs thirty-six were identified as bioaccumulative and were evaluated in the terrestrial food chain model.

7.8.3.2 Sediment

Eleven COPECs in sediment were carried forward into the BERA. When refined EPCs were compared with the ESLs, only one constituent, iron, had a refined HQ greater than 1. In addition, ESLs were not available for three other constituents (barium, beryllium, and vanadium). The BERA results for sediment COPECs at the IAA are presented in Table 7-30 and are discussed in Appendix A in detail. The inorganics, barium, iron, and vanadium, were present at background levels. Six constituents were also defined as bioaccumulative.

7.8.4 Refinement of Assessment and Measurement Endpoints for Bioaccumulative COPECs

Food chain modeling was conducted at the IAA in order to evaluate the potential ecological effects of the bioaccumulative COPEC in soil on the receptors identified in Appendix A. COPECs identified in soil and sediment were evaluated in the terrestrial and aquatic food chains, respectively. The results for both the maximum and refined scenarios of the food chain models are presented in Appendix A, and the results of each of the refined scenarios are discussed in detail in Appendix A.

7.8.4.1 Terrestrial Food chain Model

As summarized in Table 7-31, the refined scenario NOAEL and LOAEL HQs for the short-tailed shrew were generally low, but there were a few values above 1. These results are discussed in more detail in Appendix A. Based on the overall analysis of terrestrial food chain modeling HQs and consideration of the limited spatial extent of affected soils, adverse effects are not expected for short-tailed shrew (and other insectivorous mammals) and American robin (and other insectivorous birds) populations exposed to bioaccumulative COPECs in soil at the IAA.

7.8.4.2 Aquatic Food Chain Model

The results of the aquatic food chain model indicate that all HQs were below 1 for both great blue heron and mink (see Appendix A) with the exception of the zinc NOAEL HQ for mink which was 2. Given the very low exceedance and the conservatism inherent in the assessment, it was concluded that the area was unlikely to pose a significant adverse ecological impact to ecological receptors at the population-level.

7.8.5 Ecological Risk Summary

Screening-level and baseline risk assessments were completed for the IAA. After the SLERA, 53 constituents were selected as COPECs in surface soil, and 11constituents were selected as COPECs in sediment because the HQs were greater than 1, the chemical was bioaccumulative, or an HQ could not be calculated because an ESL was not available. After the BERA, all constituents in surface soil, and 10 constituents in sediment were retained. Food chain modeling was evaluated for all those constituents identified as bioaccumulative.

Tables 7-31 and 7-32 summarize the results of the food chain models, indicating a few exceedances. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents in surface soil, the potential for population-level effects is low.

Based on the overall analysis of the ERA for the IAA, the results indicate that adverse population-level effects are not expected for wildlife at the site.

7.9 IAA Summary and Conclusions

The IAA was formerly used for igniter assembly operations and the shipping and receiving of materials. Approximately 36 buildings located within the IAA were connected by raised concrete walkways, gravel paths, and paved roads. Site reconnaissance activities concluded that 29 of the buildings at the IAA contained a conductive flooring material similar to that used at the BLA. Like the BLA, all wooden roofs and walls have been removed from the IAA buildings. Exposure to the weather has caused the conductive flooring material to deteriorate into a red powder like substance and wash off onto surrounding soils.

Environmental investigations conducted at the IAA between 1997 and 2008 focused on evaluating the effects that the deteriorating conductive flooring material and historical site operations have had on the soils surrounding the IAA buildings. Soil samples were also collected at former electrical transformer locations, and from area drainage ditches. A water sample was also collected from an underground utility vault at Building 522. Laboratory analyte classes varied between the investigation activities but have included explosives, herbicides, pesticides, PAHs, PCBs, VOCs, SVOCs, TAL inorganics, asbestos, TCLP-inorganics, and lead-based paint analysis. An extensive soil sampling program was also conducted in 2008 that included screening 475 soil samples around IAA buildings for lead using XRF.

Igniter Assembly Area

The primary constituents of concern identified during the investigation at the IAA are associated with the deteriorating conductive flooring in the remains of the former IAA buildings. Inorganics, including, arsenic, barium, cadmium, cobalt, copper, iron, lead, mercury, nickel, and zinc have been detected in surface soil samples collected around the IAA buildings. Lead and copper, which are believed to have been the primary components of the conductive flooring material were the most frequently detected constituents at elevated concentrations. The 2008 sampling activities confirmed that the elevated inorganics concentrations are generally limited to surface soils (i.e., 0-1 ft bgs) immediately adjacent to (i.e. within 1 to 5 ft of) buildings with conductive flooring material; although, the elevated concentrations extend up to 15 ft from Buildings 502, 504, 522, and 522A in the southern portion of the IAA. Subsurface soil sampling activities at the IAA have indicated that the elevated inorganics concentrations associated with the flooring material are generally confined to the interval from 0 to 1 ft bgs. Only two subsurface soil samples collected from 1 to 2 ft bgs next to Building 504 had flooring related inorganics constituents (i.e., chromium, copper, lead, and zinc) at concentrations above applicable screening levels and background concentrations. Deeper samples collected from this and other areas of the site did not contain any flooring related inorganics at concentrations above applicable RSLs and background levels. Aluminum, which is not related to the flooring material was detected in two subsurface soil samples at concentrations above the residential RSL and slightly above background levels. The results of TCLP analysis of soil samples collected around IAA buildings in 2008 indicated that no constituents were present at concentrations above applicable TCLP screening levels.

Asbestos, another component of the conductive flooring and possibly other IAA building materials (e.g., pipe insulation, joint compounds, mastic, roofing materials), has been identified in surface soils surrounding the various IAA buildings. The results of the 2008 investigation indicated that the asbestos is confined to surface soils located within 1 to 5 ft of the buildings with the conductive flooring material.

The PCBs Aroclor 1254 and Aroclor 1260 were detected at concentrations above applicable screening levels in a few isolated surface soil samples collected adjacent to IAA Buildings 502, 504, 8101, 8102-5, and 8102-A. Several SVOC/PAH compounds were also detected in isolated surface soil samples at concentrations above applicable RSLs, including: bis(2-ethylhexyl)phthalate, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene.

Igniter Assembly Area

The 2002 investigation at the IAA included the collection of samples from eight former transformer locations to identify potential PCB releases. The results indicated that Aroclor 1260 was detected at a concentration slightly above the residential RSL at one location (IATR07) in the southeast portion of the IAA. PCBs were not detected above applicable screening criteria at any of the other sample locations.

No herbicides, pesticides, or VOCs were detected in IAA soils at concentrations above applicable RSLs.

The explosive compound 2,4-dinitrotoluene (DNT) was detected at concentrations above the soil RSL in two samples from a single boring location near Building 504 during the 1997 site investigation. This constituent was not detected during any of the subsequent investigations, including samples collected near the location of the original 1997 detection.

Soil/sediment samples were collected from IAA drainage ditches during the 2002 site investigation to evaluate whether constituents were being transported from the building areas. The analytical data indicated that several of the samples collected adjacent to area roadways contained PAHs, including benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene at concentrations approaching, and in some cases above applicable RSLs. As PAHs were only present in isolated surface soil samples at the IAA, these detections can likely be attributed to the asphalt from the paved road. Lead was also detected at concentrations above applicable RSLs in two samples collected from ditches that transport water from the main building area of the IAA. Additional sampling conducted in these drainage ditches during the 2008 site investigation indicated that the lead concentrations were only slightly above background and were below applicable screening levels; therefore, the previous lead detections in these areas were likely isolated and not indicative of transport within the ditches.

One water sample collected from an underground utility vault at Building 522 in 2008 did not contain any constituents at concentrations above tap water RSLs. No other surface water samples were collected during the IAA investigation, as there are no surface water bodies in the vicinity of the IAA. The drainage ditches at the IAA only carry water during heavy rainfall events.

An HHRA was conducted at the IAA to evaluate potential exposures associated with site constituents to humans. Site worker exposures to surface soil and sediment were evaluated under current and future land-use conditions; and construction worker, adult resident, and child resident exposures to total soil and sediment were evaluated under future land-use conditions.

The soil and sediment COPCs were evaluated for direct contact. VOCs identified as COPCs in the IAA were also evaluated for inhalation via vapor migration into buildings. Two VOCs, 3-octanone and d-limonene, do not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area.

A current or future site worker could be present at the IAA area, and could be exposed to surface soil or sediment. The total cumulative ELCR for site workers exposed to surface soil and sediment at the IAA is 1×10^{-4}, which is at the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 1, which is equal to the benchmark of 1. Lead was also evaluated as a COPC for the site worker scenario, although the results are reported differently than those for the other COPCs. The predicted worker blood lead levels were below the benchmark and the predicted fetal lead level was equal to the benchmark.

A hypothetical future construction worker could be present at the IAA area, and could be exposed to combined surface and subsurface soil. The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the IAA was 6×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 3, which is above the benchmark of 1. The predicted worker blood lead levels were below the benchmark and the predicted fetal lead level was equal to the benchmark.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil and sediment at the IAA is 5×10^{-4}, which is slightly above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The primary contributor to risk estimates is 2,4-dinitrotoluene in soil. Other contributors to the excess lifetime cancer risks were benzo(a)pyrene, Aroclor 1254, and arsenic.

The total cumulative HI for hypothetical future adult residents is 1, which is equal to the benchmark. The predicted adult resident blood lead levels were below the benchmark of 10 µg/dl, and the predicted fetal lead level was slightly greater than the benchmark.

The total cumulative HI for hypothetical future child residents is 13, which is above the benchmark of 1. When the HI was is segregated by target site and critical effects, hazards were greater than the benchmark of 1 due to the presence of Aroclor 1254, cobalt, and 2,4-dinitrotoluene. The predicted blood lead levels were all below the benchmark.

Although 2,4-dinitrotoluene and cobalt contributed to the elevated HI for the child resident, it should be noted that 2,4-Dinitrotoluene was detected in two of thirty samples with the two detections collected from two depths at sampling location 504360 during the December 1997 sampling event. No other detections of this constituent were confirmed during the subsequent sampling events. As for cobalt, only the maximum detected concentration (422 mg/kg) fell outside of the background concentration range of 5.9 mg/kg to 130 mg/kg. As such 2,4-dinitrotoluene and cobalt are not considered drivers for remediation at the site.

Removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and wash onto the surrounding soils. Activity based sampling conducted at the IAA has demonstrated that intensive disturbance of the soils located immediately adjacent to the buildings where the flooring has washed off the building pads has the potential to generate airborne asbestos concentrations that may present an unacceptable risk to human receptors under current/future industrial exposure scenarios and hypothetical future residential land use scenarios. Activity based sampling has also indicated that airborne asbestos fibers are not generated at distance from the buildings or where asbestos concentrations in soil are low. Soil sampling at the IAA has indicated that the elevated concentrations of asbestos in soil that have the potential to generate the airborne asbestos concentrations are primarily located immediately adjacent to the site buildings, which is the same general area where the inorganic risk drivers are located.

While not evaluated in the risk assessment any residual lead based paint on the concrete walls at the IAA or other possible asbestos containing building materials (i.e., pipe insulation, joint compounds, mastic, etc.) could also present a small risk to current and future receptors. However, it should be noted that the overall extent of these materials at the site is limited.

A SLERA and BERA were completed for the IAA, to evaluate surface soil and sediment for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial food chain models indicate that some of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils and some individual piscivorous mammals and birds exposed to sediment and/or surface water. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, effects of these COPECs at the population-level are unlikely at the IAA.

The environmental investigations completed at the IAA have successfully defined and delineated the extent of impacts that historical operations and degrading flooring material have had on environmental media at the site. The investigations have confirmed that the effects are generally limited to surface soils located immediately adjacent to buildings with conductive flooring; and in some cases near former transformers. The results of the HHRA activities indicated that asbestos in soil is the only risk driver for the industrial exposure scenario. Under the hypothetical future residential exposure scenarios, asbestos, lead and Aroclor 1254 were all identified as potential risk drivers. There is also an active source (conductive flooring) that still has the potential to release constituents into the environment. The ERA concluded that the potential adverse effects to ecological receptors is limited. .

An FS is recommended to assess potential remedial alternatives to mitigate the risks and hazards associated with the site soils, conductive flooring material, and other building materials at the IAA.

8. Rail Yard

8.1 Site Description and History

The RY encompasses an open area approximately 3,200 ft long by 350 ft wide (approximately 39 acres) in the central portion of the RFAAP-NRU (Figure 1-2). The RY was used for loading and unloading rail cars and the temporary storage of rail cars. The area contained three parallel sets of tracks and several spurs so that cars could be rearranged. Four of the spurs at the north end of the site were surrounded by earthen berms. Three open transfer platforms and one bermed transfer platform are located along the southernmost track for loading and unloading the trains. A decommissioned sewer line runs southwest from a building foundation to a branch of the RFAAP-NRU sewer system that is no longer in use.

8.2 Physical Setting

The RY area is relatively flat at an elevation of approximately 2,100 ft amsl. The area is very open with much of the site being covered with asphalt roadways, gravel, and grass groundcover (Figure 8-1). Surface water runoff from the RY is directed to two tributaries to the unnamed creek that flows through the southwest portion of the RFAAP-NRU. Engineered drainage control ditches channel runoff in the areas between the tracks, ultimately draining into one of the two tributaries.

Stratigraphic characterization of the area indicates that the subsurface consists of a layer of mostly strong brown clay with some silt to a depth of 1–2 ft below ground surface (bgs). Beneath this layer, to a depth of at least 23 ft bgs, the soil is predominantly strong brown with some yellowish-brown to yellowish-red soft to very hard clay. A surficial gravel layer to a depth of approximately 1 ft bgs exists between Track A and the four transfer platforms. The soil at the RY has been extensively reworked and is considered part of the Groseclose Urban Land Complex. The reader is referred to the *Facility-Wide Background Study Report* (IT, 2001) for detailed description of the geology and soil types for the RFAAP-NRU.

8.3 Conceptual Site Model

In accordance with the general CSM presented in Section 3.5, potentially affected media at the RY include surface soil, subsurface soil, sediment, and surface water. The most likely sources of potential contaminant releases at the site include historical train loading, unloading, and maintenance activities. Raw materials used in the historical manufacturing activities at the RFAAP-NRU and packaged explosives/propellants manufactured at the facility were unloaded/loaded onto train cars from four transfer platforms. Routine maintenance was likely performed on trains in the yard as well. Explosives, propellants, degreasers, cleaning agents, and lubricants would be included among the potential contaminants to have been released at the site. These releases would most likely have occurred along the tracks, spurs, and at the transfer platforms present at the site. PCB containing electrical transformers formerly located at the site could also have contributed to releases at the site.

Surface and subsurface soils located adjacent to the tracks, transfer platforms, and spurs are the most likely media to exhibit potential effects from historical operations. Historical sampling activities at the RY have thoroughly investigated these areas as discussed in Section 8.4.

Surface water and sediments in RY area drainage ditches, tributaries to the unnamed creek, RY area pond, and vaults under the transfer platforms would also have the potential to exhibit effects resulting from migration of contaminated media from the source areas. These areas were all included in the RY area investigations.

It should be noted that the southern tributary of the unnamed creek at the RY flows onto the RFAAP-NRU installation from off-site, and thus has the potential to carry contaminants from off-site, upstream sources.

8.4 Environmental Investigations

The RY was originally designated a Study Area for the RFAAP-NRU due to the potential for releases to have occurred from the former train loading, unloading, and storage operations conducted at the site. Environmental investigations at the RY have been on-going since 1997 and have included:

- 1997 and 1998 – Independent Sampling by Gannett Fleming
- 1998 – Remedial Investigation by ICF KE
- 2002 – Baseline Investigation by Shaw
- 2002 – Remedial Investigation by Shaw

The goals and findings of each of these investigations are summarized in the following sections. As discussed in Section 4.1, the constituent detections reported in these sections are compared to their medium specific screening criteria, where applicable.

8.4.1 Independent Sampling, Gannett Fleming, 1997 and 1998

Gannett Fleming conducted independent sampling events in 1997 and 1998 under the direction of the USEPA to evaluate the potential for contamination at the site resulting from the former rail yard operations. The following samples were collected during this investigation:

1997

- Two surface soil samples (SS-07 and SS-08)
- One sludge/sediment sample (SL-05) from a sewer system manhole

1998

- One surface soil sample (SS-08A) to confirm detections at previous sample location SS-08
- Two surface soil samples (TR-02A and TR-02C) collected near a former transformer location
- One sludge/sediment sample (SL-08) and one water sample (WW-04) from the crawlspace inside transfer platform 602
- Three sediment samples (SD-03, SD-04, and SD-05) from the tributaries to the unnamed creek

The samples from the 1997 and 1998 investigation activities were analyzed for TCL VOCs, TCL SVOCs, PCBs, pesticides, explosives, and TAL inorganics. The detected analytes for the soil samples are summarized in Table 8-1, the sludge/sediment samples are summarized in Table 8-2, and the surface water results are presented in Table 8-3. Sample locations are depicted in Figure 8-2.

8.4.1.1 1997 and 1998 Soil Sampling

The soil data from the 1997 and 1998 investigations are summarized as follows:

VOCs. One VOC, methylene chloride, was detected in soil samples SS-07, SS-08, and SS-08A (see Table 8-1). The detected concentrations were below the residential RSL. Methylene chloride was also detected in a laboratory blank sample during analysis of the sample so the detection may be associated with laboratory contamination. No other VOCs were detected in the soil samples.

Rail Yard

SVOCs. Several SVOCs were detected in the various soil samples collected during 1997 and 1998 (see Table 8-1). However, only benzo(a)pyrene at TR-02A and pentachlorophenol at TR-02C were detected a concentrations above applicable industrial RSLs. Benzo(a)anthracene, benzo(a)pyrene, and dibenzo(a,h)anthracene at TR-02A and benzo(a)pyrene at SS-08 were also detected at concentrations above residential RSLs.

PCBs*.* Aroclor 1254 was the only PCB detected in the RY soil samples (see Table 8-1). Aroclor 1254 was detected in 1997 at soil sample location SS-08 at a concentration of 1.7 mg/kg, which is above the industrial RSL of 0.74 mg/kg. This sample location was re-sampled in 1998 (SS-08a) and the analytical results indicated an Arochlor-1254 concentration of 1.0 mg/kg, which is also above the industrial RSL. No other PCBs were detected during this investigation.

Pesticides. Four pesticides (4,4'-DDE, alpha chlordane, dieldrin, and endrin aldehyde) were detected in various RY soil samples during this phase of the investigation (see Table 8-1). Dieldrin detected in sample TR-02C was the only pesticide detected at a concentration above the industrial RSL of 0.11 mg/kg. Dieldrin was not detected at any of the other sample locations. The pesticides 4,4'-DDE, alpha-chlordane and endrin aldehyde were all detected at concentrations below residential RSLs.

Explosives. The explosive 2,6-Dinitrotoluene was detected at a concentration of 0.32 mg/kg in soil sample SS-08 during the 1997 investigation (see Table 8-1). This concentration was an order of magnitude lower than the residential RSL for this compound. No other explosives were detected in the soil samples.

Inorganics. Several inorganics were detected in all of the RY soil samples (see Table 8-1). However, arsenic at sample location SS-08 was the only inorganic detected at a concentration above applicable industrial RSLs and established background concentrations. Barium at sample location SS-07 was the only constituent detected at a concentration above a residential RSL and established background concentration. The arsenic concentration was below the background level in sample SS-08a collected in 1998, which indicates the arsenic concentration detected at SS-08 in 1997 was isolated.

8.4.1.2 1997 and 1998 Sediment Sampling

The sediment samples collected from the creek tributaries during the 1998 sampling event are summarized in Table 8-2. The results indicated the following:

VOCs. Three VOCs (Acetone, 2-butanone, and methylene chloride) were detected in various sediment samples collected during the 1997-1998 investigation (see Table 8-2). However, the detected concentrations were several orders of magnitude below applicable residential RSLs. The methylene chloride detections were also qualified as having also been detected in a laboratory blank sample.

SVOCs. Several SVOCs were detected in sludge sample SL-05 and a few isolated detections were also observed in the other sediment/sludge samples. The detected constituents and concentrations are presented in Table 8-2. The analytical results indicated that benzo(a)pyrene at SL-05 was the only constituent detected above an applicable residential RSL. No other SVOCs were detected at concentrations above industrial or residential RSLs.

Pesticides. The pesticide endrin aldehyde was detected in sludge sample SL-05 and sediment sample SD-03 (see Table 8-2). The detected concentrations were orders of magnitude below industrial and residential RSLs.

Inorganics. Several inorganics were detected in all of the sediment samples (see Table 8-2). Arsenic and iron were detected in the sludge/sediment sample from SL-05 at concentrations above the industrial and residential RSLs, respectively. The detected concentrations of these constituents were also slightly above the established background levels. No other inorganics were detected at concentrations above established background levels at any of the sample locations.

8.4.1.3 1998 Surface Water Sampling

The analytical data from surface water sample (WW-04), which was collected from the crawl space of Transfer Platform 602, is presented in Table 8-3. No analytes were detected above the tap water RSLs.

8.4.2 Remedial Investigation, ICF KE, 1998

ICF KE conducted an RI at the RY in 1998 to further investigate the site. This investigation consisted of the following tasks:

Rail Yard

- Review of historical aerial photographs to assess past use patterns
- A site reconnaissance to assess current site conditions; and
- Collection of 3 surface soil samples 12 subsurface soil samples from seven soil borings (RYSB1 through RYSB7)

Aerial photographs and site reconnaissance were used to select areas where railroad cars were loaded and unloaded, and areas where rail cars were stored. These types of areas were thought to be the most likely to have been affected by historical site operations. A total of 3 surface soil and 12 subsurface soil samples were collected from seven soil borings (RYSB1 through RYSB7) during the investigation. The sample locations are depicted in Figure 8-2.

The samples collected during this investigation were analyzed for SVOCs, explosives, and TAL inorganics. The analytical results from these samples are summarized in Table 8-4. The results indicated the following:

SVOCs. There were a few isolated detections of diethylphthalate and di-n-butylphthalate in both surface and subsurface soils. However, all of the detected concentrations were several orders of magnitude below applicable industrial and residential RSLs (see Table 8-4).

Explosives. No explosives were detected in any of the samples.

Inorganics. Several inorganic constituents were detected in all of the soil samples collected during this phase of the investigation (see Table 8-4). However, the analytical results indicated that the detected concentrations were generally below established background levels and/or applicable RSLs. The only exceptions was cobalt, which was detected at a concentration of 74.9 mg/kg in surface soil (0-4 ft bgs) and 74.5 mg/kg in subsurface soil (4-6 ft bgs) at soil boring RYSB4. These concentrations were above the industrial RSL and slightly above the background level of 72.3 mg/kg. As the detected cobalt concentrations at RYSB4 were only slightly above background levels, it is likely that cobalt is naturally occurring at this location.

8.4.3 Baseline Study, Shaw, 2002

On July 25 and 26, 2002 Shaw conducted a baseline study at the RY for ATK. This sampling program was conducted to provide baseline concentrations for constituents in soil so that effects from possible future uses at the RY could be separated from existing conditions. The sampling event included the collection of thirteen surface soil samples (RYSS04 through RYSS16). The sample locations are depicted in Figure 8-2.

All of the samples collected during the baseline study sampling event were analyzed for VOCs, SVOCs, PAHs, PCBs, explosives, and TAL inorganics. Four of the 13 samples (RYSS05, RYSS09, RYSS10, and RYSS15) were also analyzed for pesticides and herbicides. The laboratory analytical results from this sampling event are summarized in Table 8-5. The results indicated the following:

VOCs. Five VOCs (acetone, ethanol, methylene chloride, 2-butanone and 3-octanone) were detected sporadically in the surface soil samples. However, all of the detected concentrations were several orders of magnitude below residential RSLs (see Table 8-5).

SVOCs/PAHs. Seventeen different PAH compounds were detected via SVOC analyses and PAH analyses (see Table 8-5). The SVOC analysis at sample location RYSS07 indicated that the PAH benzo(a)pyrene was detected at a concentration above the industrial RSL and the PAHs benzo(a)anthracene, benzo(b)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene were detected at concentrations above residential RSLs. However, the more sensitive PAH analysis at this location indicated that only benzo(a)pyrene was present at a concentration above residential RSL. Benzo(a)pyrene was also detected above the residential RSL at RYSS05. No other PAHs or SVOCs were detected at concentrations higher than residential RSLs.

PCBs. Aroclor 1254 was detected in three samples (RYSS05, RYSS07, and RYSS11). The detected concentration at RYSS07 was above the industrial RSL for this constituent, while the other detections were below the residential RSL (see Table 8-5).

Pesticides. Alpha-BHC was detected at sample locations RYSS05, RYSS09, RYSS10, and RYSS15. Beta-BHC was detected at sample locations RYSS05 and RYSS10. All of the detected concentrations were several orders of magnitude below the residential RSLs (see Table 8-5). No other pesticides were detected in the samples.

Herbicides. No herbicides were detected in any of the surface soil samples.

Explosives. No explosives were detected in any of the surface soil samples.

***Inorganics*.** Several inorganics were detected in all of the soil samples. However, the detected concentrations were all below established background levels or the applicable industrial and residential RSLs (see Table 8-5). .

8.4.4 Remedial Investigation, Shaw, 2002

During 2002 Shaw completed remedial investigation activities at the RY to further evaluate potential effects from historical operations at the site. The sampling strategy was primarily designed to collect samples in uncharacterized portions of the site, in drainage pathways leading from the site, and for analysis of analyte classes for which the site had not previously been tested. The sampling activities included:

- Eight surface soil samples (RYSS01, RYSS02, RYSS03, RYSB08, RYSB09, RYTR01, RYTR02, and RYTR03).
- Three subsurface soil samples from two borings (RYSB08 and RYSB09)
- Five sediment samples (RYSD01, RYSD07, RYSD08, RYSD09, and RYSD10) from area drainage ditches.
- Five sediment samples from the tributaries of the unnamed creek (RYSD03, RYSD05, RYSD06, RYSD12, and RYSD13)
- One sediment sample (RYSD04)and one surface water sample (RYSW04) from the RY pond.
- Five surface water samples (RYSW03, RYSW05, RYSW12, and RYSW13) from the tributaries of the unnamed creek
- One surface water sample (RYSW02)collected from the spring at the north end of the RY pond.
- One surface water sample (RYSW15) from transfer platform 602.

8.4.4.1 2002 Soil Sampling

The soil samples collected during Shaw's 2002 RI investigation were analyzed for VOCs, SVOCs/PAHs, PCBs, pesticides, herbicides, explosives, and TAL inorganics. The analytical results, which are summarized in Table 8-6, indicated the following:

VOCs. VOCs were not detected in any of the surface or subsurface soil samples.

***SVOCs/PAHs*.** Several SVOCs and PAHs were detected at various sampling locations (see Table 8-6); however, all of the detected constituents were at concentrations lower than the residential RSLs.

Rail Yard

PCBs. Aroclor 1254 was detected in surface soil samples RYSS03 and RYTR02 at concentrations slightly above the residential RSL of 0.22 mg/kg. Sample RYTR02 was collected specifically to check a former transformer location identified on a utility map of the RY. Sample RYSS03 was collected to confirm a PCB detection in historical sample SS-08. PCBs were not detected at any of the other sample locations.

Pesticides. Pesticides were not detected in any of the surface or subsurface soil samples.

Herbicides. Herbicides were not detected in any of the surface or subsurface soil samples.

Explosives. 2,4-Dinitrotoluenne was detected in one surface soil sample (RYSS03) and 4-Amino-2,6-Dinitrotoluene was detected in the subsurface soil (4-6 ft bgs) sample at RYSS08. The detected concentrations of both constituents were several orders of magnitude below residential RSLs (see Table 8-6). No other explosives were detected in any of the surface or subsurface soil samples.

Inorganics. Several inorganics were detected in all of the surface and subsurface soil samples (see Table 8-6). All of the detected inorganics were at concentrations that were either below established background levels and/or applicable industrial and residential RSLs.

8.4.4.2 2002 Sediment Sampling

Sediment samples were collected from the northern tributary to the unnamed creek (RYSD03, RYSD05, and RYSD06), southern tributary to the unnamed creek (RYSD12 and RYSD13), RY pond (RYSD04), and RY area drainage ditches (RYSD01, RYSD07, RYSD08, RYSD09, and RYSD10). The sediment samples were analyzed for VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides, explosives, and TAL inorganics. The analytical results for these samples are summarized in Table 8-7.

VOCs. Acetone, 2-butanone, and carbon disulfide were detected in sediment samples RYSD03, RYSD04 from the northern tributary to the unnamed creek and RYSD05 from the RY pond. All of the detected concentrations were several orders of magnitude less than residential RSLs (see Table 8-7). It is likely that these constituents are related to laboratory contamination as the sample results were qualified due to laboratory blank detections.

Rail Yard

SVOCs/PAHs. Seventeen PAHs were detected as a result of the PAH and SVOC laboratory analyses (see Table 8-7). Benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene were the only constituents detected at concentrations above residential RSLs. No PAHs were detected above industrial RSLs.

PCBs. No PCBs were detected in the sediment samples.

Pesticides. Fifteen different pesticides were detected in various sediment samples (see Table 8-7). None of the detected constituent concentrations were above residential RSLs.

Herbicides. Seven herbicides (1,4,5-T, 2,4,5-TP, 2,4-D, dalapon, dicamba, dichlroprop, and MCPP) were detected sporadically in the sediment samples. All of the detected concentrations were several orders of magnitude below residential RSLs (see Table 8-7).

Explosives. The explosive pentaerythritol tetranitrate was detected in two of the sediment samples collected from site drainage ditches (RYSD08 and RYSD09). Nitroglycerine was detected in two samples (RYSD03 and RYSD05) collected from the northern tributary to the unnamed creek. The detected concentrations of both constituents were below residential RSLs. No other explosives were detected in any of the samples.

Inorganics. As with all soil and sediment samples collected at the RY and across the RFAAP-NRU, several inorganics were detected in the sediment samples collected during this investigation (see Table 8-7). All of the detected inorganics were at concentrations that were either below established background levels and/or applicable industrial and residential RSLs.

8.4.4.3 2002 Surface Water Sampling

During the 2002 investigation, surface water samples were collected from the northern tributary to the unnamed creek (RYSW03 RYSW05, and RYSW06), the southern tributary to the unnamed creek (RYSW12 and RYSW13), the pond at the RY (RYSW04), the spring at the RY (RYSW02) and from underneath transfer platform 602 (RYSW15). The samples collected during this event were analyzed for VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides, explosives, inorganics, perchlorate, and hardness. The laboratory analytical results for these samples are summarized in Table 8-8.

VOCs. Chloroform was detected at a concentration greater than the tap water RSL in the surface water samples collected from the southern tributary (RYSW12 and RYSW13). Carbon disulfide was also detected in RYSW12 and RYSW05. The concentrations of carbon disulfide were below the tap water RSL. No other VOCs were detected in surface water.

SVOCs. Five SVOCs [benzoic acid, bis(2-ethylhexyl)phthalate, butylbenzylphthalate, diethylphthalate, and di-n-butylphthalate] were detected sporadically in the surface water samples (see Table 8-8). Bis(2-ethylhexyl)phthalate was detected at a concentration above the tap water RSL at sample locations RYSW04 as a result of the SVOC analysis. No other SVOCs/PAHs were detected above tap water RSLs.

PAHs. Three PAHs (2-methylnaphthalene, naphthalene, and phenanthrene) were detected in a limited number of the surface water samples (see Table 8-8). The detected concentrations were all below applicable tap water RSLs.

PCBs. PCBs were not detected in any of the surface water samples.

Pesticides. The pesticide dieldrin was detected at a concentration above the tap water RSL in the two of the surface water samples (RYSW12 and RYSW13) collected from the southern tributary of the unnamed creek. It should be noted that dieldrin was also detected in an upstream sample (WBGSW14; see Table 9-12) at a concentration above the tap water RSL. The WBGSW14 sample was collected from the stream before it enters the RFAAP-NRU facility; which indicates that dieldrin was likely from an off-site source.

Herbicides. MCPA and MCPP were detected at sample location RYSW12 at concentrations above their applicable tap water RSLs (see Table 8-8). These constituents were not detected in any other surface water samples at the RY.

Explosives. Nitroglycerine, nitrobenzene, and m-nitrotoluene were detected in surface water samples. The detected concentrations were all lower than the tap water RSLs (see Table 8-8).

Inorganics. Several inorganics were detected in the surface water samples, but no constituents were detected at concentrations above the tap water RSLs (see Table 8-8).

Perchlorate. Perchlorate was not detected in any of the surface water samples.

8.5 Nature and Extent of Constituent Detections

The sampling programs conducted at the RY were designed to provide a thorough assessment on whether environmental media was affected by historical operations at the site. The sampling activities discussed in the previous sections included a total of 32 surface soil samples, 12 subsurface soil samples, 16 sediment samples, and 8 surface water samples. Based on the results of the sampling activities, there do not appear to be any significant elevated concentrations present at the RY.

8.5.1 Soil

The soil sampling activities at the RY focused on areas near the rail lines, rail spurs, transfer platforms, building egress points, transformer locations, and other areas that may have been affected by historical operations at the RY. Laboratory analytes varied between the sampling events but included explosives, herbicides, pesticides, PAHs/SVOCs, PCBs, VOCs, and inorganics. Comparison of the collected data with the RSLs and background inorganic concentrations indicated that very few of the detected constituents were above applicable screening criteria. A site map depicting the inorganic constituents detected in the RY soils is presented in Figure 8-3. A second site map depicting the organic constituents detected in the RY soils is presented in Figure 8-4.

Arsenic, barium, and cobalt were each detected in one location at concentrations above applicable RSLs and established background levels. Arsenic was detected in 1997 soil sample SS-08 at a concentration of 20.8 mg/kg, which is above the industrial RSL of 1.6 mg/kg and slightly above the background concentration of 15.8 mg/kg. A second sample collected at this location in 1998 (SS-08A) did not have any inorganics detected above background concentrations. Barium was detected at a concentration of 1,770 mg/kg in surface soil sample SS-07 in 1997, which is higher than the residential RSL of 1,500 mg/kg and the established background level of 209 mg/kg. When this location was sampled again in 2002 (RYSS02) no inorganics were detected above established background levels. As the elevated concentrations of arsenic and barium could not be confirmed, they are both considered to be anomalies. Cobalt was detected in surface and subsurface soil at 1998 soil boring RYSB4 at concentrations slightly above the established background and the industrial RSL. No other inorganics were detected at the site at concentrations above applicable RSLs and/or background levels.

Rail Yard

The PCB Aroclor 1254 was detected in three surface soil samples (SS-08, SS-08A,and RYSS03) collected adjacent to transfer platform 602. The concentrations detected at SS-08 (1.7 mg/kg) and SS-08A (1.0 mg/kg), which were at identical locations, were above the industrial RSL of 1.0. The concentration of Aroclor 1254 detected at RYSS03 (0.37 mg/kg), which was collected adjacent to the SS-08 samples, was slightly above the residential RSL of 0.22 mg/kg. Aroclor 1254 was not detected in other soil samples collected in this area.

Aroclor 1254 was detected in one other soil sample at the RY (RYSS07) which was near a bermed transfer platform in the northeast portion of the site. The detected concentration (1.2 mg/kg) was above the industrial RSL. Other samples collected in this area did not contain any PCB detections. PCBs were not detected above applicable residential RSLs at any of the three former transformer locations sampled in 2002 (RYTR01 through RYTR03).

The pesticide dieldrin and the SVOC pentachlorophenol were detected in one sample (TR-02C) located next to a former pole mounted transformer. The concentrations of dieldrin (0.27 mg/kg) and pentachlorophenol (830 mg/kg) were both above the industrial RSL. These constituents, which are typically associated with wood preservatives and pesticides used on utility poles, were not present in a second sample (TR02A) at this location or within any other soil samples at the RY. Therefore, neither of these constituents is considered an environmental concern at this site.

Seventeen different PAH compounds were detected in soil samples at the RY using both general SVOC analysis methods and the more specific PAH analysis method. The PAH analyses indicated that benzo(a)pyrene was the only PAH constituent detected above applicable residential RSLs. Benzo(a)pyrene was detected in two samples (RYSS05 and RYSS07) at concentrations slightly above the residential RSL of 0.015 mg/kg. The SVOC analyses indicated that benzo(a)pyrene, benzo(a)anthracene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene were present in one sample (TR-02A) at concentrations above applicable RSLs; however, a second sample collected adjacent to this sample TR-02C had no PAHs detected. The PAHs that were detected at the majority of the soil sampling locations were several orders of magnitude below applicable residential RSLs.

8.5.2 Sediment

A total of 16 sediment samples were collected during the course of the investigation activities at the RY. The sample locations included surface water drainage pathways, tributaries of the unnamed creek that pass near the RY, a small pond located downgradient of the RY, a spring that feeds the pond, and sludge from the sewer system. These sample locations were selected to identify constituents that may have been transported from the RY. A site map depicting inorganic constituents detected in sediment is presented as Figure 8-5. A site maps depicting organic constituents detected in sediment is presented as Figure 8-6.

A total of seventeen different PAHs were detected at four of the sediment sample locations(RYSD01, RYSD03, RYSD04, and RYSD06); however only four of these constituents [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene] were detected at concentrations above residential RSLs. Sample location RYSD01, which was from a RY area drainage ditch, contained benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene at concentrations slightly above residential RSLs. Sample locations RYSD03 and RYSD06, which were from the northern tributary of the unnamed creek, contained benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene at concentrations above residential RSLs. PAHs were not detected above residential RSLs at any of the other sample locations.

The analytical results indicated that herbicides, pesticides, explosives were detected at low concentrations in some of the sediment samples from the RY. Where detected, the constituent concentrations were generally several orders of magnitude below applicable residential RSLs. Many of the detected constituents were not detected in soil at the RY suggesting that the constituents are not migrating from the RY.

Several inorganics were detected in all of the sediment samples collected at the RY. The majority of the detected inorganics were at concentrations below the established background concentrations for the facility and/or tap water RSLs. However, iron and vanadium were detected in one sample (RYSD08) at concentrations slightly above background and residential RSLs. These constituents were not detected at elevated concentrations in soil at the RY, and the detected concentrations in the sediment are only slightly above background; therefore, the detections are not considered to be site related.

8.5.3 Surface Water

A total of 8 surface water samples were collected during the course of the investigation activities at the RY. The sample locations generally corresponded with sediment sample locations and included tributaries of the unnamed creek that pass near the RY,

Rail Yard

a small pond located downgradient of the RY, and a spring that feeds the pond. Two water samples were also collected from a crawl space under transfer platform 602. These sample locations were selected to identify constituents that may have been transported from the RY. A site map depicting inorganic constituents detected in surface water is presented as Figure 8-7. A site map depicting organic constituents detected in surface water is presented as Figure 8-8.

Two herbicides (MCPA and MCPP) and one pesticide (dieldrin) were detected in a surface water sample (RYSW12) from the southern tributary of the unnamed creek at concentrations above the tap water RSLs. These constituents were also detected in a surface water sample collected upstream of the RY, at the WBG (WBGSW08) on the same date (June 25, 2002). Therefore, these constituent detections are not attributed to the RY.

Chloroform and bis(2-ethylhexyl)phthalate were detected in two surface water samples each. These constituents were not detected in soil at the site and are common laboratory contaminants; as such, the detections in surface water are not believed to be site related.

Several inorganics were detected in the surface water samples; however, all of the detected concentrations were below applicable tap water RSLs.

Surface Water samples WW-04 and RYSW15 were collected from the crawl space underneath transfer platform 602. The analytical results did not indicate the presence of any constituents at concentrations above tap water RSLs.

8.6 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. Risk assessment datasets for soil, sediment, and surface water for the RY were prepared then summarized and statistically analyzed. Risk assessment datasets summaries highlighting the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPC are presented in Tables 8-9 through 8-13.

8.7 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with constituents detected in soil, sediment and surface water samples collected at the RY. The risk assessment approach follows the Radford Army Ammunition Plant Final Master Work Plan (URS 2003). This section summarizes the occurrence of constituents in each medium and identifies COPCs at the RY for the human health risk assessment; identifies the potential human exposure scenarios relevant to the RY; and presents the estimated human health risks associated with the identified COPCs and the relevant human exposure scenarios at the RY. Methodologies for data summary and selection of COPCs, exposure assessment, and toxicity assessment for the HHRA were presented in Appendix A.

8.7.1 Selection of Constituents of Potential Concern

This section discusses the selection of COPCs for the HHRA for each medium at the RY.

8.7.1.1 Surface Soil

Surface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 8-14 presents the selection of surface soil COPCs for the HHRA. As summarized in Table 8-14, 14 constituents were identified as COPCs in surface soil:

- **VOCs:** 3-octanone and ethanol;
- **SVOCs:** carbazole and pentachlorophenol;
- **Pesticides:** dieldrin;
- **PAHs:** benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene;
- **PCB:** Aroclor 1254; and
- **Inorganics:** aluminum, arsenic, barium, and cobalt.

8.7.1.2 Combined Surface and Subsurface Soil

Combined surface and subsurface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 8-15 presents the selection of combined surface and subsurface soil COPCs for the HHRA. As summarized in Table 8-15, 14 constituents were identified as COPCs in combined surface and subsurface soil:

- **VOCs:** 3-octanone and ethanol;
- **SVOCs:** carbazole and pentachlorophenol;
- **Pesticides:** dieldrin;
- **PAHs:** benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene;
- **PCB:** Aroclor 1254; and
- **Inorganics:** aluminum, arsenic, barium, and cobalt.

8.7.1.3 Sediment

Sediment COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 8-16 presents the selection of sediment COPCs for the HHRA. As summarized in Table 8-16, 12 constituents were identified as COPCs in sediment:

- **Explosives:** pentaerythritol tetranitrate;
- **Herbicides:** dichlorprop;
- **PAHs:** benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene; and
- **Inorganics:** aluminum, arsenic, cobalt, iron, manganese, and vanadium.

8.7.1.4 Surface Water

Surface water COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for tap water. Table 8-17 presents the selection of surface water COPCs for the HHRA. As summarized in Table 8-17, 9 constituents were identified as COPCs in surface water:

- **VOCs:** chloroform;
- **SVOCs:** bis(2-ethylhexyl)phthalate.;
- **Explosives:** nitroglycerine;
- **Herbicides:** MCPA and MCPP;
- **Pesticides:** dieldrin; and

Inorganics: iron, lead, and manganese.

8.7.2 Human Health Risk Characterization

The physical and chemical properties and toxicity values used to evaluate excess lifetime cancer risks and non-cancer hazards are presented in Appendix A. The exposure assumptions used to evaluate potentially exposed receptors are presented in Appendix A. The equations used in the risk characterization calculations are also presented in Appendix A. The EPCs are provided in Table 8-18.

Exposure to the soil, sediment, and surface water COPCs were evaluated for direct contact. VOCs identified as COPCs in the RY were also evaluated for inhalation via vapor migration into buildings. Two VOCs, 3-octanone and ethanol, were identified as soil COPCs at the RY. These COPCs do not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area.

The excess lifetime cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the RY are presented in Appendix A and are summarized in the table and subsections below.

Rail Yard

Summary of Calculated ELCRs and HIs for Receptor Exposure Scenarios

RECEPTOR/ EXPOSURE MEDIUM – SCENARIO	Total ELCR	HI
Site Worker		
Surface Soil - Direct Contact	1E-04	0.3
Sediment – Wading	8E-07	0.01
Surface Water – Wading	2E-07	0.1
TOTAL SITE RISKS (Site Worker):	**1E-04**	**0.4**
Hypothetical Future Construction Worker		
Combined Surface and Subsurface Soil - Direct Contact	5E-06	0.7
TOTAL SITE RISKS (Construction Worker):	**5E-06**	**0.7**
Hypothetical Future Adult Resident		
Combined Surface and Subsurface Soil - Direct Contact	-	0.3
Sediment – Wading	-	0.02
Surface Water – Wading	-	0.2
TOTAL SITE RISKS (Adult Resident):	**-**	**0.6**
Hypothetical Future Child Resident		
Combined Surface and Subsurface Soil - Direct Contact	**-**	**3**
Sediment – Wading	-	0.1
Surface Water – Wading	-	0.1
TOTAL SITE RISKS (Child Resident):	**-**	**3**
Hypothetical Future Resident (Adult and Child)		
Combined Surface and Subsurface Soil - Direct Contact	3E-04	**-**
Sediment – Wading	3E-06	-
Surface Water – Wading	1E-06	-
TOTAL SITE RISKS (Resident):	**3E-04**	**-**

*See Appendix A for individual tables.

8.7.2.1 Site Worker

A current or future site worker could be present at the RY area, and could be exposed to surface soil, sediment, or surface water. The ELCR and non-cancer hazard index for site worker exposure to each medium are presented in Appendix A, and are summarized in Table 8-19. As presented in the table above, the ELCRs for surface soil, sediment, and surface water are all below or within the USEPA target risk range, and the HIs for each medium are all below the benchmark value of 1.

The total cumulative ELCR for site workers exposed to surface soil, sediment, and surface water at the RY is 1×10^{-4}, which is at the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.4, which is less than the benchmark of 1.

8.7.2.2 Hypothetical Future Construction Worker

A hypothetical future construction worker could be present at the RY area, and could be exposed to combined surface and subsurface soil. The ELCR and non-cancer hazard index for hypothetical future construction worker exposure to soil are presented in Appendix A, and are summarized in Table 8-19. As presented in the table above, the ELCR for combined surface and subsurface soil is within the USEPA target risk range, and the HI is below the benchmark value of 1.

The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the RY was 5×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 0.7, which is less than the benchmark of 1.

8.7.2.3 Hypothetical Future Residents

A hypothetical future resident could be present at the RY area, and could be exposed to combined surface and subsurface soil, sediment, or surface water. The ELCR and non-cancer hazard index for hypothetical future resident exposure to each medium are presented in Appendix A, and are summarized in Table 8-19. The ELCRs are all below or within the USEPA target risk range, with the exception of hypothetical future residential exposure to combined surface and subsurface soil. Similarly, the HIs for each medium are all below the benchmark value of 1, with the exception of child resident exposure to combined surface and subsurface soil.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water at the RY is 3×10^{-4}, which is slightly above the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The primary risk driver is pentachlorophenol (PCP) in soil. PCP was detected at a concentration greater than the industrial RSL (9 mg/kg) in one surface soil sample [TR-02C (830 mg/kg)] which was collected in 1998 at a former pole-mounted transformer location. The concentration of PCP in a duplicate surface soil sample collected at this location (TR-02A) was only 0.11mg/kg. A total of 33 soil samples (20 surface soil samples and 13 subsurface soil samples) collected during subsequent investigations at the Rail Yard were analyzed for PCP. PCP was not detected in any of these samples, nor was PCP detected in any surface water or sediment samples at the Rail Yard. As PCP is known to have been used as a wood preservative for utility poles, the single elevated detection of PCP at sample location TR-02C has been linked to the former utility pole at this sample location. The observation that PCP was not detected at elevated levels in the duplicate sample at this location, or in any other soil samples at the site, indicates that the elevated detection was limited to the area in the immediate vicinity of the utility pole.

The total cumulative HI for hypothetical future adult residents is 0.6, which is less than the benchmark of 1.

The total cumulative HI for hypothetical future child residents is 3, which is greater than the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were only above the benchmark of 1 in the eyes, nails, hair, and skin. The primary contributor to the non-cancer hazard above 1 is cobalt. The maximum cobalt concentration of 74.9 mg/kg is only slightly greater than the background concentration of 72.3 mg/kg and is well within the range of background levels. Therefore, it is likely that cobalt is present due to naturally occurring sources rather than due to activities at the RY.

8.7.3 Human Health Risk Summary

Table 8-19 summarizes the calculated cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the RY. As shown in the table above, the total ELCR values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below or within the benchmark range of 10^{-6} to 10^{-4} for cancer risk, with the exception of hypothetical future residential exposure to combined surface and subsurface soil. This is due to the presence of pentachlorophenol, which was detected in two samples, one at an estimated value of 0.11 mg/kg and one at a maximum concentration of 830 mg/kg. The one high detection was from a sample collected in April 1998, and the results have not been duplicated in subsequent sampling. The risk assessment was based on the maximum detected concentration at this single sample location and thus may overestimate potential exposures. Without pentachlorophenol as a risk driver, the ELCR would be 3×10^{-5} which is within the target range for cancer risk.

The total HI values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below the benchmark of 1 for non-cancer hazard, with the exception of hypothetical future child resident exposure to combined surface and subsurface soil. The risk driver for non-cancer hazard is cobalt. The maximum cobalt concentration of 74.9 mg/kg is only slightly greater than the background concentration of 72.3 mg/kg and is well within the range of background levels. Therefore, it is likely that cobalt is present due to naturally occurring sources rather than due to activities at the RY.

The results of the human health risk assessment indicate that use of the RY for industrial or residential uses should not result in unacceptable risks to potential receptors.

8.8 Ecological Risk Assessment

The purpose of the ERA is to evaluate whether ecological receptors may be adversely impacted by exposure to site-related constituents detected in surface soil, sediment, and surface water at the RY. This ERA is intended to provide input for risk management decision-making for the RY, while maintaining a conservative approach protective of wildlife populations and communities. In accordance with USEPA guidance, the ERA for the RY commenced with a SLERA and then concluded with BERA (USEPA 1997c).

This section summarizes the occurrence of constituents in each medium and identifies COPECs at the RY for the ecological risk assessment; identifies the potential ecological exposure scenarios relevant to the RY; and presents the estimated ecological risks associated with the identified COPECs and the relevant ecological exposure scenarios at the RY. Methodologies for data summary and selection of COPECs, exposure assessment, and toxicity assessment for the ERA were presented in Appendix A.

8.8.1 Selection of Constituents of Potential Ecological Concern

This section discusses the selection of COPECs for each medium. Risks to ecological receptors are calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the hazard quotient (HQ), is a highly conservative surrogate for the assessment endpoints identified in Appendix A. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse ecological effects are unlikely (USEPA 1997c). HQs greater than 1 indicate that further evaluation is warranted. Therefore, the constituents with HQs greater than 1 or that are bioaccumulative, are carried forward as COPECs into the BERA. Maximum HQs greater than 1 for the RY are summarized in the subsections below.

8.8.1.1 Surface Soil

Surface soil COPECs were selected by comparing the analytical data with USEPA (2005b) EcoSSLs, USEPA (2003e) Region 5 ESLs, and ORNL values (Efroymson et al. 1997a,b) for surface soil. Table 8-20 presents the selection of surface soil COPECs for the ERA. As summarized in Table 8-20, 42 constituents were identified as COPECs in surface soil:

- **VOCs:** 3-octanone and ethanol;
- **SVOCs:** 2,6-dinitrotoluene, benzoic acid, bis[2-ethylhexyl[phthalate, carbazole, dibenzofuran, di-n-butylphthalate, and pentachlorophenol;
- **Explosive:** 4-amino-2,6-dinitrotoluene;
- **Pesticides:** 4,4'-DDE, alpha-BHC, beta-BHC, alpha-chlordane, dieldrin, and endrin aldehyde;
- **PAHs:** acenaphthene, acenaphthylene, anthracene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, phenanthrene, and pyrene
- **PCB:** Aroclor 1254;
- **Inorganics:** aluminum, antimony, arsenic, barium, cadmium, cobalt, copper, lead, mercury, selenium, and zinc.

8.8.1.2 Sediment

Sediment COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008c) Region 3 Sediment Screening Levels; ORNL values (Jones et al. 1997); and USEPA (2003e) Region 5 Ecological Screening Levels for sediment. Table 8-21 presents the selection of COPECs for the HHRA. As summarized in Table 8-21, 54 constituents were identified as COPECs in sediment:

- **VOCs:** 2-butanone, acetone, and carbon disulfide;

- **SVOCs:** bis(2-ethylhexyl)phthalate;

- **Explosives:** nitroglycerine and pentaerythritol tetranitrate;

- **Herbicides:** dalapon, dicamba, dichlorprop, and MCPP;

- **Pesticides:** 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, alpha-BHC, delta-BHC, gamma-BHC, alpha-chlordane, gamma-chlordane, dieldrin, endosulfan II, endrin, heptachlor, heptachlor epoxide, and methoxyclor,

- **PAHs:** 2-methylnaphthalene, acenaphthene, acenaphthylene, anthracene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, phenanthrene, and pyrene,

- **Inorganics:** arsenic, cadmium, lead, nickel, selenium, zinc, barium, beryllium, chromium, copper, iron, manganese, thallium, and vanadium.

8.8.1.3 Surface Water

Surface water COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Surface Water Screening Levels; ORNL values (Suter and Tsao 1996); USEPA (2003e) Region 5 Ecological Screening Levels; and USEPA (2008e) Ambient Water Quality Criteria for surface water. Table 8-22 presents the selection of COPECs for the HHRA. As summarized in Table 8-22, 17 constituents were identified as COPECs in surface water:

- **Herbicides:** 2,4-DB, MCPA, and MCPP;

- **Pesticides:** 4,4'-DDT, delta-BHC, dieldrin;

- **PAHs:** Phenanthrene

- **Inorganics:** aluminum, barium, cadmium, chromium, copper, iron, lead, selenium, silver, and zinc.

One spring sample (RY_SPRING00Y) was also evaluated for surface water COPECs by comparing the analytical data with background spring data as well as ESLs. As shown in the table below, two PAHs and nine inorganics were detected in the spring sample. Four of the inorganics are vital electrolytes and/or essential nutrients (calcium, magnesium, potassium, and sodium) and therefore were identified as non-toxic and not evaluated further. Only two of the inorganics, aluminum and iron, were detected above the background concentrations or were above the corresponding ESL as discussed below.

Aluminum and iron were both detected above the ESL and the background spring sample concentrations. While the detected concentration of aluminum was above the ESL, the ESL used is from USEPA (2009) Region 3 and is based on a water quality criterion protective of salmonids (i.e., coldwater habitat species of fish such as trout and salmon) which is likely overly conservative for the type of warm-water habitat (and associated aquatic species) that is prevalent in this locale. When an alternative screening value for aluminum of 0.46 mg/L from Sample et al. 1996 was used, an HQ of less than 1 was calculated. This alternative screening value is based on the lowest chronic value for aquatic life, and is considered to be a more representative screening value for aluminum at the RY than the Region 3 ESL.

For iron, although the detected concentration was above the ESL, the spring water sample was not filtered, and as such the results represent total iron. Therefore, it is not known what portion, if any, of the iron is in the dissolved (i.e., filtered) form. It is possible that even though the total iron concentrations exceed the ESL, the dissolved (and therefore bioavailable) iron concentrations may in actuality not exceed the ESL. Based on these considerations, adverse effects to aquatic life potentially exposed to inorganics at the RY are unlikely.

Comparison of ELs and Background Spring Data

Constituent	ESL (µg/L)	Background Spring Data NSPRING003 09/24/08	NSPRING004 09/24/08	RY_SPRING002 09/24/08	Does Max Exceed ESL or BKG?
PAHs					
Naphthalene	**1.1**	<0.092	<0.092	0.044	no

µg/L Micrograms per liter.
NT Non-toxic.

8.8.2 Summary of Selected Constituents of Potential Ecological Concern

Forty-two constituents were selected as COPECs in surface soil, fifty-four constituents were selected as COPECs in sediment, and seventeen constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was bioaccumulative, or an HQ could not be calculated because an ESL was not available.

8.8.3 Refinement of Risk Calculations for Direct Contact COPECs

The list of COPECs identified in the BERA was reevaluated by calculating refined HQs. The refined HQs were calculated for the COPECs identified in the SLERA using refined EPCs. Constituents identified as COPECs in the BERA that were bioaccumulative were carried forward into food chain models. The results of the recalculation of the HQs for the RY are summarized in the subsections below.

8.8.3.1 Surface Soil

Forty-two COPECs in surface soil were carried forward into the BERA. When refined EPCs were compared with the ESLs, 10 constituents (2,6-dinitrotoluene, pentachlorophenol, 4,4'-DDE, dieldrin, endrin aldehyde, cobalt, lead, selenium, and zinc) had a refined HQ greater than 1. In addition, ESLs were not available for seven other constituents (3-octanone, ethanol, benzoic acid, carbazole, dibenzofuran, Aroclor 1254, and lead). The BERA results for surface soil COPECs at the RY are presented in Table 8-23 and are discussed in Appendix A in detail.

Of the COPECs, twenty were also identified as bioaccumulative and were evaluated in the terrestrial food chain model.

8.8.3.2 Sediment

Fifty-four COPECs in sediment were carried forward into the BERA. When refined EPCs were compared with the ESLs, 12 constituents [2-butanone, acetone, carbon disulfide, alpha-chlordane, gamma-chlordane, dieldrin, endrin, heptachlor epoxide, acenaphthene, acenaphthylene, indeno(1,2,3-cd)pyrene, and iron], had a refined HQ greater than 1. In addition, ESLs were not available for 10 other constituents (nitroglycerine, pentaerythritol tetranitrate, dalapon, dicamba, dichlorprop, MCPP, barium, beryllium, and vanadium). The BERA results for sediment COPECs at the RY are presented in Table 8-24 and are discussed in Appendix A in detail. The results of the BERA indicate that adverse effects to aquatic life due to potential explosive exposure are considered unlikely. Of the COPECs twenty-eight were identified as bioaccumulative and were evaluated in the aquatic food chain model.

8.8.3.3 Surface Water

Seventeen COPECs in surface water were carried forward into the BERA. When refined EPCs were compared with the ESLs, eight constituents (4,4'-DDT, aluminum, barium, copper, iron, lead, silver, and zinc) had a refined HQ greater than 1. In addition, ESLs were not available for three other constituents (2,4-DB, MCPA, and MCPP). The BERA results for surface water COPECs at the RY are presented in Table 8-25 and are discussed in Appendix A. It is unlikely that adverse effects to aquatic life would occur due to the low frequency of detection, the low detected concentrations, and comparison to available screening levels (for the inorganics).

Of the COPECs 10 were identified as bioaccumulative and were evaluated in the aquatic food chain model.

8.8.4 Refinement of Assessment and Measurement Endpoints for Bioaccumulative COPECs

Food chain modeling was conducted at the RY in order to evaluate the potential ecological effects of the bioaccumulative COPECs in soil, sediment, and surface water on the receptors identified in Appendix A. COPECs identified in soil were evaluated in the terrestrial food chain, and COPECs identified in sediment and surface water were evaluated in the aquatic food chain. The results for both the maximum and refined scenarios of these models are presented in Appendix A and the results of each of the refined scenarios are discussed in the subsections below.

8.8.4.1 Terrestrial Food chain Model

As summarized in Table 8-26, the refined scenario NOAEL and LOAEL HQs for both the short-tailed shrew and the American robin were less than or equal to 1 for most of the bioaccumulative COPECs identified at the RY. Based on the overall analysis of terrestrial food chain modeling HQs and consideration of the limited spatial extent of impacted soils, adverse effects are not expected for short-tailed shrews (and other insectivorous mammals) and American robins (and other insectivorous birds) populations exposed to bioaccumulative COPECs in soil at the RY.

8.8.4.2 Aquatic Food chain Model

As summarized in Table 8-27, the refined scenario NOAEL and LOAEL HQs for both the mink and the great blue heron were less than or equal to 1 for all of the bioaccumulative COPECs identified in sediment and/or surface water, with the exception of the mink NOAEL (HQ=40) and LOAEL (HQ=4) for zinc. This inorganic was not identified as a direct contact COPEC for sediment following the refined evaluation because it had a refined direct contact HQ of less than 1. However, because zinc was identified as a bioaccumulative COPEC in surface water, it was included in the food chain modeling.

As previously discussed, the NOAEL, is a very conservative screening criterion, while the LOAEL indicates a concentration above which adverse impacts to individual mammals may occur. Based on this information and considering the low frequency of detection of this constituent these results indicate that individual mink and herons (or other piscivorous mammals and birds) exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of aquatic food chain modeling HQs, adverse effects are not expected for mink (and other piscivorous mammals) and great blue herons (and other piscivorous birds) populations potentially exposed to bioaccumulative COPECs in sediment and/or surface water at the RY.

8.8.5 Ecological Risk Summary

Screening-level and baseline risk assessments were completed for the RY. After the SLERA, 42 constituents were selected as COPECs in surface soil, 54 constituents were selected as COPECs in sediment, and 17 constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was bioaccumulative, or an HQ could not be calculated because an ESL was not available. After the BERA, 36 constituents in surface soil, 50 constituents in sediment, and 16 constituents in surface water were retained because the HQs were greater than 1, the chemical was bioaccumulative, or an HQ could not be calculated because an ESL was not available. Food chain modeling was evaluated for all those constituents identified as bioaccumulative.

Tables 8-28 and 8-29 summarize the constituents in surface soil, sediment, and surface water carried through the BERA and evaluated in the terrestrial and/or aquatic food chain models. As shown in these tables, all constituents evaluated in the terrestrial and aquatic food chain refined scenarios had LOAEL and NOAEL HQs less than or equal to 1, with the exception of shrew HQs for pentachlorophenol and zinc and mink HQs for zinc. However, these HQs are based on the very conservative screening criterion of the NOAEL. In addition, there was a low frequency of detection of pentachlorophenol in surface soil and the EPC for zinc is very similar to its established site background concentration. Furthermore, zinc was not identified as a direct contact COPEC for sediment, indicating that direct contact of ecological receptors with zinc in the sediment is not expected to result in any adverse effects. These results indicate that individual shrews (or other insectivorous mammals) and individual minks (or other piscivorous mammals) potentially exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of the ERA for the RY, the results indicate that adverse effects are not expected for wildlife at the site.

8.9 RY Summary and Conclusions

The RY encompasses an open area approximately 3,200 ft long by 350 ft wide (approximately 39 acres) in the central portion of the RFAAP-NRU. The RY was used for loading and unloading rail cars and the temporary storage of rail cars. Environmental investigations conducted at the RY between 1997 and 2002 included the collection of surface soil and subsurface soil samples from various areas of the site, including: along the railroad tracks and spurs; adjacent to transfer platforms and former building locations; near former electrical transformer locations; and in area drainage pathways. Surface water and sediment samples were also collected from the pond and streams located in the vicinity of the RY. Laboratory analyte classes varied between the investigation activities but have included explosives, herbicides, pesticides, PAHs, PCBs, VOCs, SVOCs, and TAL inorganics. The investigation activities were conducted to evaluate whether the RY was affected by historical operations at the site, and if so were constituents of concern migrating away from the site.

The extensive soil sampling activities at the RY indicated that there were limited sporadic detections of compounds at concentrations above applicable screening levels. However, there was no pattern of spatial distribution or indication of source areas. PCBs were not detected at any of the former transformer locations. Subsurface soil sampling activities also indicated no evidence of significant constituent concentrations in the subsurface. Offsite surface water and sediment gave no indication of being affected by constituents migrating from the site. Based on the

Rail Yard

compiled data from the various phases of investigation at the site, there do not appear to be significant elevated concentrations of contaminants at the RY.

The HHRA for the RY evaluated current and future land-use conditions for site workers and hypothetical future use for construction workers and adult and child residents. Exposure of these receptors to the soil, sediment, and surface water COPCs was evaluated in the risk assessment. Although exposure to VOCs in soil migrating into buildings was identified as a potential exposure pathway, inhalation toxicity values were not available for the two VOCs, 3-octanone and ethanol, identified as soil COPCs at the RY. Therefore, this exposure pathway was not evaluated quantitatively.

A current or future site worker could be present at the RY area, and could be exposed to surface soil, sediment, or surface water. The total cumulative ELCR for site workers exposed to surface soil, sediment, and surface water at the RY is 1×10^{-4}, which is equal to the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.4, which is less than the benchmark of 1.

A hypothetical future construction worker could be present at the RY area, and could be exposed to combined surface and subsurface soil. The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the RY is 5×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 0.7, which is less than the benchmark of 1.

A hypothetical future resident could be present at the RY area, and could be exposed to combined surface and subsurface soil, sediment, or surface water. The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water at the RY is 3×10^{-4}, which is slightly above the high end of the USEPA target risk range of 10^{-6} to 10^{-4}. This risk driver for cancer risk is pentachlorophenol, which was detected in two samples, one at an estimated value of 0.11 mg/kg and one at a maximum concentration of 830 mg/kg. The one high detection was from a sample collected in April of 1998 and the results were not duplicated in subsequent sampling. The risk assessment was based on the maximum detected concentration and thus likely overestimates potential exposures.

The total cumulative HI for hypothetical future adult residents is 0.6, which is less than the benchmark of 1.

Rail Yard

The total cumulative HI for hypothetical future child residents is 3, which is greater than the benchmark of 1. The primary contributor to the non-cancer hazard above 1 is cobalt. The maximum cobalt concentration of 74.9 mg/kg is only slightly greater than the background concentration of 72.3 mg/kg and is well within the range of background levels. Therefore, it is likely that cobalt is present due to naturally occurring sources rather than due to activities at the RY.

A SLERA and BERA were completed for the RY, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that a few of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils and some individual piscivorous mammals and birds exposed to sediment and/or surface water, if all exposure assumptions are met. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, adverse impacts at the population level are considered unlikely for the shrew (or other insectivorous mammals) and the robin (or other insectivorous birds) exposed to the constituents at the RY.

The investigation activities performed at the Rail Yard did not identify any significant evidence of potential adverse affects to environmental media at the site as a result of historic operations. The results of the human health risk assessment indicate that use of the Rail Yard for residential or industrial uses should not result in unacceptable risks to potential receptors. The ERA also indicated that no adverse impacts would be expected to ecological receptors on a population level. Therefore, No Action is recommended for this site.

9. Western Burning Ground

9.1 Site Description and History

The WBG is a former burning ground located in the southwestern portion of the RFAAP-NRU, south of the IAA (Figure 1-2). The WBG was used during historical operations and during the subsequent facility decommissioning process as a burning ground to decontaminate explosives contaminated material and to dispose of excess and off-spec explosives/energetics. The main burn area was approximately 170 ft long by 100 ft wide and is surrounded on three sides by an approximately 4 ft high earthen berm. A dirt road runs parallel to the open side of the former burn area, leading north to Alger Road, and south to the top of a steep slope above an unnamed pond. The dirt road was reportedly constructed on top of an ashy layer of material extending from the burning ground at the time of the pond construction. The pond was constructed during the early 1990s and is fed by Wiggins Spring at the northwest (upgradient) end of the pond. The pond also collects runoff from the surrounding area through a series of storm water ditches/culverts. The WBG is no longer active. A site map depicting the relevant features of the WBG site is presented as Figure 9-1.

9.2 Physical Setting

The WBG area is generally flat at an elevation of approximately 2,050 ft amsl but slopes increase to the south and southwest towards Wiggins Spring and an unnamed pond. Surface water runoff from the former burn area is expected to flow to the southwest. A small, unlined drainage ditch captures some runoff, channeling flow to the northwest before intersecting a second ditch that drains into the pond. The site is surrounded with wooded areas.

The unnamed pond, which is approximately 3.6 acres in size, was constructed south of the WBG during the early 1990s. The pond is fed by Wiggins Spring, a natural spring located at the head (i.e., northwest corner) of the pond. The pond also collects surface water drainage from the surrounding area. The pond drains under an earthen dam via a constant level drain on the southeastern side of the pond. The effluent flows into a tributary of the unnamed creek that flows through the southwest portion of the RFAAP-NRU.

Stratigraphic characterization within the area generally indicates that the subsurface consists of a layer of brownish-yellow, hard to very hard, clay that is variably mixed with gray gravel, to a depth of approximately 6 ft. An approximately 3.5 ft thick brownish-yellow soft clay seam underlies the hard clay. Below this layer, the soil grades to a gray, hard saprolitic clay (weathered bedrock product). Within the bermed burn area, the depth to bedrock was slightly shallower, ranging from1 ft at the northern end to 4 ft at the southern end, as measured during a test pitting program conducted during 1999 RI activities. Based on the Facility-Wide Background Study Report (IT 2001), soils at the site have been characterized as Lodi loam. The Lodi loam is a member of the Wurno-Newbern-Faywodd Silt Loam complex and is characterized by a moderate permeability and typical depth to bedrock of 4 to 6 ft.

9.3 Conceptual Site Model

In accordance with the general CSM presented in Section 3.5, media that could potentially have been affected by the historical burning ground operations performed at the WBG include surface soil, subsurface soil, sediments, and surface water. Based on the results of historical sampling activities at the site, surface soils within the bermed area where the burning activates were performed are known to have contained several COPCs at concentrations above applicable screening criteria. Site restoration activities completed in this area in 1999 included the removal of surface and subsurface soils and the placement of clean backfill; therefore, the former burn area is no longer considered an area of potential concern.

During site investigation activities a layer of ashy material was identified underneath a dirt road than runs along the open side of the former burning area. This road was constructed during the 1990s to provide access to the newly constructed pond. The ashy material is believed to be material that was pushed out of the burning ground area during historical operations and was subsequently buried during road construction activities. Historical subsurface and surface soil samples from this area have delineated the extent of the ashy layer in the subsurface and sampling has not identified evidence of COPCs at concentrations above screening levels; therefore, this area is not considered to be an area of potential concern.

Surface water and sediment are present in the man-made pond and the unnamed creek that received drainage from the pond at the WBG. Historical sampling conducted in both the pond and the creek have identified the presence of COPCs. Both of these resources could have been affected by COPCs that migrated from the source area due to surface water runoff prior to the site restoration activities. It is also possible that grading activities conducted during the pond and access road construction activities in the 1990s moved soils and COPCs from the source area.

9.4 Environmental Investigations

The WBG was originally designated a Study Area for the RFAAP-NRU due to the former burning ground operations conducted at the site. Environmental investigations at the WBG have been on-going since 1997 and have included:

- 1997 – Independent Sampling by Gannett Fleming
- 1998 and 1999 – Remedial Investigation by ICF KE
- 2002 – Remedial Investigation by Shaw
- 2004 – Additional Characterization Sampling by Shaw
- 2008 – Remedial Investigation by ARCADIS

The goals and findings of each of these investigations are summarized in the following sections. As discussed in Section 4.1, the constituent detections reported in the investigation summaries are compared to their medium specific screening criteria, where applicable.

9.4.1 Independent Sampling, Gannett Fleming, 1997

Gannett Fleming conducted an independent sampling event in 1997 under the direction of the USEPA to evaluate the potential contamination at the site resulting from the former burning ground operations. The following samples were collected during this investigation:

- Three surface soil samples (SS-04, SS-04a, SS-05)
- Two co-located surface water/sediment samples (SW/SD-01 and SW/SD02)

The three soil samples were analyzed for TCL VOCs, TCL SVOCs, PCBs, explosives, dioxins/furans, and TAL inorganics. The laboratory analytical results for the soil samples are summarized in Table 9-1 and the sample locations are depicted in Figure 9-2. The results indicated the following.

VOCs. Three VOCs (acetone, carbon disulfide, and methylene chloride) were detected in the soil samples. The detected concentrations of these constituents were all several orders of magnitude lower than residential RSLs.

SVOCs. Two SVOCs [Bis(2-ethylhexyl)phthalate and di-n-butylphthalate] were detected in soil samples (see Table 9-1). The detected concentrations were several orders of magnitude below the residential RSLs.

PCBs. Aroclor 1254 was the detected at sample locations SS-04 and SS-04a (see Table 9-1). The detected concentrations were lower than the residential RSL. No other PCBs were detected in the soil samples.

Explosives. No explosives were detected in the soil samples.

Dioxins/Furans. Several dioxin/furan compounds were detected in the soil samples (see Table 9-1 for complete list). The detected concentrations were all below applicable residential RSLs.

Inorganics. Several inorganic constituents were detected in all of the soil samples. However, the detected concentrations were all below established background levels and/or applicable RSLs (see Table 9-1).

The sediment samples (SD-01 and SD-02) and surface water samples (SW-01 and SW-02) were collected from the northeastern portion of the unnamed pond. The sample locations are depicted in Figure 9-2 and the laboratory analytical results are presented in Tables 9-2 and 9-3, respectively. The sediment and surface water results indicated the following:

VOCs. Four VOCs (2-butanone, acetone, methylene chloride and toluene) were detected in the two sediment samples (see Table 9-2). The detected concentrations were all lower than applicable residential RSLs.

SVOCs. Ten VOCs were detected in the sediment samples (see Table 9-2 for complete list). Benzo(a)pyrene was detected at SD-01 at a concentration above the residential RSL. No other constituents were detected at concentrations above applicable RSLs.

PCBs. No PCBs were detected in the sediment samples.

Pesticides. No pesticides were detected in the sediment samples.

Inorganics. Several inorganic constituents were detected in the sediment samples. However, the detected concentrations were all below established background levels and/or applicable RSLs (see Table 9-2). Inorganics detected in surface water samples were all below applicable tap water RSLs (see Table 9-3).

9.4.2 Remedial Investigation, ICF KE, 1998 and 1999

ICF KE conducted an RI at the WBG in 1998 and 1999 to characterize the site. The first phase of this RI included:

- A bottom coil Geonics EM61 geophysical survey to identify buried debris
- The collection of five surface soil samples and three subsurface soil samples from five soil borings (WBG-SB1 through WBG-SB5) in the former burn area.
- The collection of three co-located surface water (WBGSW1, WBGSW2, and WBGSW3) and sediment samples (WBGSD1, WBGSD2, and WBGSD3).

The second phase of the RI included the following activities:

- Collection of 27 soil samples from 17 soil borings in and around the former burning area, including
    - o Six soil samples from the berm area surrounding the former burning area (WBGSB6 through WBGSB11):
    - o 19 soil samples from 10 borings (WBGSB12 through WBGSB21) along the access road to the unnamed pond).
    - o Two soil samples from the location of a burn cage stored at the WBG (WBGBC1A, WBGBC1B)
- Excavation of 19 test pits to characterize the subsurface in the burning area
- Collection of 43 confirmatory samples to ensure that the test pits were excavated to a sufficient depth
- Advancement of 9 soil borings to determine the extent of the ashy layer extending from the burn area.
- Collection of three co-located surface water (WBGSW4, WBGSW5, and WBGSW6) and sediment samples (WBGSD4, WBGSD5, and WBGSD6) from the unnamed pond.

9.4.2.1 Geophysical Survey *and 1998 Soil Sampling Activities*

A Geonics EM61 bottom coil geophysical survey was conducted within the former burn area to identify areas that contained elevated concentrations of buried metallic debris. The results of the survey identified five geophysical anomalies that were selected for further investigation through the collection of soil samples The findings of the geophysical survey are summarized in the *Results of Geophysical Investigation Report (ICF KE, 1998)*.

Western Burning Ground

Five soil borings were completed (WBGSB1 through WBGSB5) in the former burn area using direct-push sampling technology to investigate the anomalies identified in the geophysical survey. A thin ashy layer of material was encountered at approximately 0.5 – 2 ft bgs during advancement of the soil borings. Surface soil samples (0-2 ft bgs) were collected at each of the boring locations to characterize the ashy material. Subsurface soil samples were also collected at the WBGSB1 boring (2-4 ft bgs) and the WBGSB2 boring (6-8 ft bgs and 9-11 ft bgs). All samples were analyzed for TCL VOCs, TCL SVOCs, explosives, and TAL inorganics,. The analytical results from these samples are summarized in Table 9-4. The results indicated the following:

VOCs. Methylene chloride was detected in the surface soil samples at WBGSB2 and WBGSB4. The detected concentrations were several orders of magnitude below residential RSLs (See Table 9-4). Methylene chloride is a common laboratory contaminant.

SVOCs. As indicated in Table 9-4, several SVOCs were detected in a limited number of the soil samples. Benzo(a)pyrene was detected above the industrial RSL in the near surface soil samples at WBGSB3 and WBGSB4. Benzo(a)anthracene and benzo(b)fluoranthene were also detected at concentrations above residential RSLs at these locations. No other PAH compounds were detected at concentrations above applicable RSLs.

Explosives. No explosives were detected in any of the soil samples.

Inorganics. Several inorganics were detected in all of the soil samples (See Table 9-4). A limited number of the inorganic constituents (antimony, arsenic, barium, copper, lead, and zinc) were detected at concentrations above background levels and applicable RSLs.

- Lead was detected in the surface soil samples at WBGSB1 (2,070mg/kg) WBGSB2 (2,450 mg/kg), WBGSB3 (3,990 mg/kg) and WBGSB4 (2,480 mg/kg) at concentrations higher than industrial RSLs and background levels. The lead concentrations in all of the subsurface samples were below residential RSLs.
- Antimony, arsenic, barium, copper, and zinc concentrations were also elevated compared to background concentrations in several of the surface soil samples and were higher than residential screening levels in at least one of the samples. The inorganics concentrations in the subsurface samples were less than established background levels.

9.4.2.2   1999 Soil Sampling Activities

Nine soil borings (WBGPB1 through WBGPB6 and WBGQSB1 through WBGQSB3) were advanced in 1999 to evaluate the extent of the subsurface ash layer identified in the burn area during the 1998 sampling event. The findings from this investigation indicated that ash was present in five of six borings (WBGPB1 through WBGPB5) advanced along the dirt road leading to the unnamed pond. Ash was not encountered in the boring located furthest from the burn area along the road (WPGWB6) or in three borings (WBGQSB1 through WBGQSB3) advanced south of southern berm around the burn area. The ash layer was reported to have ranged in thickness from approximately 2 inches to 1 ft in the areas it was detected. The ash layer was generally encountered from 2 to 4 ft bgs. The ashy layer appears to have been buried when the pond access road was constructed. The boring locations are depicted in Figures 9-2 and 9-3.

Based on the presence of the ashy layer underneath the road, an additional 10 soil borings (WBGSB12 through WBGSB21) were advanced along the unpaved road to further evaluate soil quality. The boring locations are depicted in Figures 9-2 and 9-3. Surface soil samples (0-2 ft bgs) and subsurface soil samples (2-4 ft bgs) were collected from the WBGSB13 through WBGSB21 borings. The sample at WBGSB12 was collected from 0-4 ft bgs. All of the soil samples collected during this investigation were analyzed for TCL SVOCs and TAL inorganics. The laboratory analytical results are summarized in Table 9-5. The results indicated the following:

SVOCs. SVOCs were not detected in any of the surface or subsurface soil samples.

Inorganics. Several inorganic constituents were detected in all of the surface and subsurface soil samples (see Table 9-5). However, the detected concentrations were all below established background levels and/or applicable industrial and residential RSLs.

Six surface soil samples (WBGSB6 through WBGSB11) were collected from soil borings competed on the berm surrounding the former burning area. The samples were collected from 0-2 ft bgs; deeper samples were not collected at these locations due to refusal on shallow bedrock. The samples were analyzed for TCL VOCs, TCL SVOCs, PAHs, explosives, TAL inorganics, pH, and TOC (one sample). The sample locations are depicted in Figures 9-2 and 9-3 and the analytical results are summarized in Table 9-5.

VOCs. Two VOCs were detected in the soil samples (see Table 9-5). Acetone was detected at WBGSB10 and p-isopropyltoluene was detected at WBGSB8. The detected concentrations were several orders of magnitude below applicable RSLs.

SVOCs. Di-n-butylphthalate was the only SVOC detected in the berm area samples (see Table 9-5). The detected concentrations were all several orders of magnitude below applicable RSLs.

PAHs. Three PAHs (acenaphthylene, benzo(b)fluoranthene, and pyrene) were detected at concentrations below residential RSLs at WBGSB9 (see Table 9-5). No other PAHs were detected at any of the sample locations.

Explosives. No explosives were detected in any of the samples.

Inorganics. Several inorganics were detected in all of the berm area soil samples (see Table 9-5). The detected concentrations were all below established background levels and/or applicable RSLs with the exception of arsenic at sample location WBGSB8. Arsenic was detected at a concentration higher than the industrial RSL and slightly above the established background at WBGSB8. It should be noted that the arsenic concentration in a duplicate sample collected at WBGSB8 was 15.8 mg/kg, which is equal to the established background concentration.

These results suggest that ash from the burning activities was not mixed with the soil in the berm. The berm was likely constructed from native soil in the area prior to the initiation of burning activities at the WBG.

Two soil samples [WBGBC1A (0-2 ft bgs) and WBGBC1B (5-7 ft bgs)] were collected from a soil boring located underneath a former burn cage at the WBG. These samples were analyzed for TCL SVOCs and TAL inorganics. The analytical results from these samples, which are presented in Table 9-5, indicated that inorganics concentrations were within normal background levels. The only SVOC detected, bis(2-ethylhexyl)phthalate, was detected at a concentration (0.040 mg/kg) several orders of magnitude less than the residential RSL of 35 mg/kg. The results suggest that the burn cage had been moved to this location and was not actually used at this sample location.

9.4.2.3 1999 Test Pitting and Confirmatory Sampling

In 1999, 19 test pits were advanced in the former burn area to characterize the subsurface conditions. Because of elevated inorganics concentrations, soils excavated during the test pitting activities was disposed off-site. The excavation of the test pits effectively removed soils containing elevated constituent concentrations inside the bermed area where the burning operations were conducted. A total of 19 samples (WBGDW1 through WBGDW7 and WBGDW15 through WBGDW26) were collected from the excavated material and submitted for laboratory analysis of TCLP-inorganics. None of the detected analytes were above applicable TCLP standards. The analytical results from the excavated/stockpiled soils are summarized in Table 9-6.

A total of 43 confirmatory soil samples (WBGTP1A through WBGTP19S) were collected from the base of the test pits to verify that the excavation activities were effective at removing the soils affected by the former burning activities. All of the samples were analyzed for TAL inorganics. Seven of the samples (WBGTP2B, WBGTP7A, WBGTP10B, WBGTP12A, WBGTP12S, WBGTP18A, and WBGTP19A) were also analyzed for TCL SVOCs, pH, and dioxins/furans. The sample locations are depicted in Figure 9-3 and the laboratory analytical results are summarized in Table 9-7. The results indicate the following:

SVOCs. Several SVOCs were detected in isolated samples collected during the test pit confirmation sampling program (see Table 9-7). Benzo(a)pyrene was detected at sample locations WBGTP3A and WBGTP9A at concentrations above the residential RSL. Dibenzo(a,h)anthracene also was detected at a concentration above the residential RSL at WBGTP9A (0.20 mg/kg). No other SVOCs were detected at concentrations above applicable industrial or residential RSLs.

Dioxins/Furans. As indicated in Table 9-7, several dioxins and furans were detected in the soil samples analyzed for this group of constituents. However, the dioxin 1,2,3,7,8-PeCDD at sample location WBGTP2B was the only constituent detected at a concentration above an applicable residential RSL.

Inorganics. The inorganics concentrations detected in 42 of the 43 confirmation samples were either below the residential RSLs or established background levels (see Table 9-7). Lead was detected at a concentration of 808 mg/kg at sample location WBGTP1B (3.5 - 4 ft bgs) which is above the industrial RSL of 800 mg/kg. The test pitting activities had removed all soil to top of bedrock at this location, therefore no additional soil was excavated.

9.4.2.4 1998 and 1999 Sediment and Surface Water Sampling

Three co-located surface water/sediment samples were collected from the WBG in 1998. Two of these samples (WBGSD/SW2 and WBGSD/SW3) were collected from the unnamed pond and one (WBGSD/SW1) was collected from the unnamed creek downstream from the pond. These samples were analyzed for TCL VOCs, TCL SVOCs, explosives, and TAL inorganics,. Three additional co-located sediment and surface water samples were collected from the unnamed pond (WBGSD/SW4, WBGSD/SW5, and WBGSD/SW6) in 1999. These samples were analyzed for TCL SVOCs, TAL inorganics, perchlorate (surface water), and total organic carbon. The sample locations are depicted in Figure 9-2. The analytical results for the sediment samples are summarized in Table 9-8, and the analytical results for the surface water samples are summarized in Table 9-9.

The analytical results for the sediment samples indicated:

VOCs. Two VOCs (acetone and toluene) were detected at low concentrations in 1998 samples WBGSD1, WBGSD2, and WBGSD3 (see Table 9-8). The detected concentrations were several of orders of magnitude below residential RSLs. No VOCs were detected in the 1999 sediment samples.

SVOCs. 4-Methylphenol at WBGSD2 and bis(2-ethylhexyl)phthalate at WBGSD5 were the only SVOCs detected in the sediment samples (See Table 9-8). The detected concentrations were below applicable residential RSLs.

Explosives. No explosives were detected in the sediment samples.

Inorganics. The detected inorganics concentrations generally corresponded with background inorganics concentrations for the site. However, lead was detected at sample location WBGSD5 at a concentration of 347 mg/kg, which is greater than the established background of 26.8 mg/kg. A second sample was collected at the WBGSD5 location in 1999 that resulted in a lead concentration of 899 mg/kg, which is higher than the industrial RSL of 800 mg/kg.

The analytical results for the surface water samples indicate:

VOCs. Chloroform and 2-butanone were detected at sample location WBGDW2 and were the only VOCs detected in the surface water samples (see Table 9-9). The concentration of chloroform at WBGSW2 was above the tap water RSL.

SVOCs. Diethylphthalate at WBGSW1 and di-n-butylphthalate at WBGSW6 were the only SVOCs detected in the surface water samples (see Table 9-9). The detected concentrations were several orders of magnitude below applicable tap water RSLs.

Explosives. No explosives were detected in any of the surface water samples.

Inorganics. Several inorganic constituents were detected in the surface water samples (See Table 9-9). However, arsenic at WBGSW5 and WBGSW6 and thallium at WBGSW1 were the only constituents detected at concentrations above tap water RSLs.

Perchlorate. Perchlorate was not detected in any of the surface water samples.

9.4.3 Remedial Investigation, Shaw, 2002

During 2002 Shaw completed remedial investigation activities at the WBG to further evaluate soil quality to the north and west of the former burn area, and near a former transformer location, Surface water and sediment samples were also collected from the unnamed pond, downstream creek, and area drainage pathways. Activities completed during this phase of the investigation included:

- Four soil borings (WBGSB22 through WBGSB25) to evaluate surface and subsurface soil quality to the west and northwest of the former burn area. Samples were collected at 0-0.5 ft bgs, 2-4 ft bgs, and 6-8 ft bgs at each boring.
- Collection of one surface soil sample (WBGTR01) near a former transformer location to evaluate whether PCBs were present.
- Nine co-located surface water/sediment samples (WBGSW/SD07 through WBGSW/SD15) to further evaluate sediment and surface water quality in the unnamed pond, downgradient stream, and area drainage pathways.

The sample locations from this investigation are depicted in Figure 9-2.

9.4.3.1 2002 Soil Sampling

The soil samples collected from the four soil borings (WBGSB22 through WBGSB25) were analyzed for VOCs, SVOCs/PAHs, PCBs, explosives, dioxins/furans, and inorganics. The surface soil samples collected at each boring location were also analyzed for herbicides and pesticides. The surface soil sample at the former transformer location was only analyzed for PCBs. The analytical results from the 2002 soil sampling activities are summarized in Table 9-10. The results of the sampling activities indicated:

VOCs. Acetone, carbon disulfide, d-limonene, and toluene were detected in a limited number of the soil samples (see Table 9-10). However, the detected concentrations were several orders of magnitude below applicable residential RSLs.

SVOCs/PAHs. Seventeen PAHs and five non-PAH SVOCs were detected in various soil samples (see Table 9-10). One PAH, benzo(a)pyrene, was detected in surface soil at WBGSB24 and WBGSB25 at concentrations above the industrial RSL. Benzo(a)pyrene was also detected above the industrial RSL in the 2-4 ft bgs sample at WBGSB22. The PAHs, benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were also detected in surface soil at WBGSB24 and WBGSB25, and subsurface soil at WBGSB22, at concentrations above residential RSLs. No other PAH/SVOC constituents were detected at concentrations above residential RSLs.

PCBs. One PCB, Aroclor 1254 was detected in the 2-4 ft bgs sample collected at soil boring WBGSB22. The detected concentration 0.87 mg/kg is higher than the industrial RSL of 0.74 mg/kg. Aroclor 1254 was not detected in the surface soil sample or the 6-8 ft bgs sample at WBGSB22. PCBs were not detected in any of the other soil samples, including at the former transformer location (WBGTR01).

Pesticides. 4,4'-DDD was detected in surface soil at WBGSB25 (0.0019 mg/kg) and dieldrin was detected in surface soil at WBGSB24 (0.00472 mg/kg). The detected concentrations of both constituents were below residential RSLs. No other pesticides were detected in the soil samples.

Herbicides. Four herbicides (2,4,5-TP, 2,4-D, dalapon, and MCPP) were detected in the surface soil samples. The detected concentrations were all lower than residential RSLs.

Explosives. Pentaerythritol Tetranitrate was detected at a concentration of 0.11 mg/kg in the surface soil sample at WBGSB24 (see Table 9-10). There is not an established RSL for this constituent. No other explosives were detected in any of the soil samples.

Dioxins/Furans. Several dioxins/furans were detected in both the surface and subsurface soil samples at WBGSB22 through WBGSB25 (see Table 9-10). 1,2,3,7,8-

PeCDD, detected in the 2-4 ft bgs sample at WBGSB22, was the only compound detected at a concentration above residential RSLs.

Inorganics. Several inorganics were detected in all of the soil samples (see Table 9-10). The 2-4 ft bgs sample from WBGSB22 contained lead (965 mg/kg) and arsenic (29 mg/kg) at concentrations above industrial RSLs and background levels. Iron (61,800 mg/kg) was also detected in this sample at a concentration above the residential RSL and background. This sample location corresponds with a subsurface layer of ashy material detected underneath the pond access road. The surface soil sample and the 6-8 ft bgs sample at WBGSB22 did not contain arsenic, iron, or lead at concentrations above residential RSLs and background. The other soil borings did not contain inorganics at concentrations above residential RSLs and background levels, with the exception aluminum in subsurface soil (6-8 ft bgs) at WBGSB23. The concentrations of aluminum was only slightly above the established background concentrations at the referenced location.

9.4.3.2 2002 Sediment Sampling

A total of 9 sediment samples were collected in 2002 (WBGSB07 through WBGSB15). Four of the samples (WBGSD07, WBGSD10, WBGSD11, and WBGSD12) were collected from the unnamed pond. Three of the samples (WBGSD08, WBGSD09, and WBGSD13) were collected from the stream downgradient of the pond. Sample WBGSD14 was collected from the unnamed creek that runs through the southwest portion of the RFAAP-NRU, upstream of the confluence with the pond effluent stream. WBGSB15 was collected from a drainage pathway located upgradient (west) of the pond. The samples were analyzed for VOCs, SVOCs/PAHs, PCBs, pesticides, herbicides, explosives, dioxins/furans, inorganics, and total organic carbon. The analytical results from these samples are presented in Table 9-11. The results indicated:

VOCs. Four VOCs (2-butanone, acetone, carbon disulfide, and toluene) were detected in sediment samples (see Table 9-11). However, the detected concentrations were several orders of magnitude below applicable residential RSLs. These constituents were also detected in laboratory blank samples; therefore, it is likely that the reported concentrations are due to laboratory contamination.

SVOCs/PAHs. Seventeen PAHS and six non-PAH SVOCs were detected in sediment samples (see Table 9-11). Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene were detected at WBGSD09 at concentrations above industrial RSLs. Benzo(a)pyrene was also detected at WBGSD07 and WBGSD14 at concentrations above the industrial RSL. Benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were detected at concentrations above residential RSLs at WBGSD07 and WBGSD14.

PCBs. No PCBs were detected in the sediment samples.

Pesticides. The pesticides 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, alpha-chlordane, delta-BHC, dieldrin, Endosulfan, endrin aldehyde, endrin ketone, gamma-chlordane, and methoxychlor were detected in several sediment samples (see Table 9-11). All of the detected constituents were below applicable residential RSLs. It should also be noted that pesticides were also detected in WBGSD14 and WBGSD15 which were collected from an unnamed stream outside the boundaries of the RFAA-NRU. These samples were collected from an upstream location and were outside the influence of the RFAAP-NRU, therefore it is likely that the detected pesticides can be attributed to an off-site source.

Herbicides. Four herbicides (2,4,5-TP, 2,4-D, dicamba, and MCPP) were detected in sediment samples (see Table 9-11). The detections, all of which were below residential RSLs, occurred in WBGSD8 and WBGSD14.

Explosives. 1,3,5-trinitrobenzene and nitroglycerine were detected at WBGSD12 at concentrations of 0.41 mg/kg and 0.96 mg/kg, respectively. The nitroglycerine concentration was above the residential RSL. No other explosives were detected in sediment samples.

Dioxins/Furans. Several dioxins/furans were detected in the sediment samples from the pond and downgradient stream (see Table 9-11). All of the detected concentrations were below applicable residential RSLs.

Inorganics. Several inorganics were detected in all of the sediment samples (see Table 9-11). Chromium (15,400 mg/kg), cobalt (84.1 mg/kg), lead (109,000 mg/kg) and zinc (17,300 mg/kg) were detected in pond sediment sample WBGSD10 at concentrations above both residential and/or industrial RSLs, as well as background levels. Arsenic was detected in stream samples WBGSD9 (16.6 mg/kg) and WBGSD13 (30.4 mg/kg) at concentrations above industrial RSLs and slightly above established background levels. Iron was also detected in stream sample WBGSD13 (293,000 mg/kg) at a concentration above the residential RSL and background level.

9.4.3.3 2002 Surface Water Sampling

Surface water samples were collected in conjunction with the nine sediment samples discussed in the previous section. The surface water samples were analyzed for VOCs, SVOCs/PAHs, PCBs, pesticides, herbicides, explosives, dioxins/furans, inorganics, and perchlorate. The laboratory analytical results from these samples are summarized in Table 9-12.

VOCs. Seven VOCs [acetone, carbon disulfide, chloroform, cis-1,2-dichloroethene (cis-1,2-DCE), tetrachloroethene (PCE), toluene, and trichloroethene (TCE)] were detected in surface water samples during this phase of investigation (see Table 9-12). Three of these constituents (cis-1,2-DCE, PCE, and TCE) were only detected in sample WBGSW14, which was collected from the unnamed stream that runs through the southwest portion of the RFAAP-NRU, prior to the confluence with the WBG stream and upstream of the RFAAP-NRU facility boundary. The concentration of PCE in this sample was higher than the tap water RSL. Chloroform was also detected at a concentration greater than the tap water RSLs at WBGSW08 , WBGSW09, and WBGSW10.

SVOCs/PAHs. Six PAHS and seven non-PAH SVOCs were detected in surface water samples (see Table 9-12). None of the detected constituents were at concentrations above their respective tap water RSL.

PCBs. No PCBs were detected in the surface water samples.

Pesticides. Dieldrin was detected at WBGSW08, WBGSW13, and WBGSW14 (see Table 9-12). The concentrations detected at WBGSW08 and WBGSW14 were higher than the tap water RSL. No other pesticides were detected in surface water.

Herbicides. The herbicide MCPP was detected at WBGSW08 at a concentration above the tap water RSL (see Table 9-12). The herbicide 2,4-D was also detected at WBGSW08 and WBGSW14, although the concentrations were below tap water RSLs.

Explosives. The explosive m-nitrotoluene was detected at WBGSW08 and WBGSW09 (see Table 9-12). There is no tap water RSL for this constituent.

Dioxins/Furans. The dioxin OCDD was detected at WBGSD07, WBGSW08, WBWSW09, and WBGSW10 (see Table 9-12). The detected concentrations were below the tap water RSL. No other dioxins or furans were detected in surface water samples.

Inorganics. Iron (50,900 µg/L) and manganese (1,470 µg/L) were detected at concentrations higher than the tap water RSL at WBGSW13. No other inorganics were detected at concentrations above the tap water RSLs (see Table 9-12).

Perchlorate. Perchlorate was detected in surface water sample WBGSW14 (see Table 9-12). The detected concentration was below the tap water RSL.

9.4.4 Additional Characterization, Shaw, 2004

Shaw completed additional sampling activities at the WBG site in 2004 that were designed to further assess the horizontal and vertical extent of constituents detected in surface and subsurface soil extending from the burning ground. The investigation also included additional assessment activities for the unnamed pond. Activities completed during this investigation included:

- Collection of 54 surface soil samples, 27 subsurface soil samples and 14 pond sediment samples for lead field screening using XRF technology.
- Collection of 21 surface soil samples and 10 subsurface soil samples from 28 soil borings (WBGSB26 through WBGSB53) for laboratory analysis.
- Collection of 10 sediment samples (WBGSD16 through WBGSD25) from the unnamed pond for laboratory analysis.
- A fish tissue/bioaccumulation sampling event for the unnamed pond.

9.4.4.1 2004 Soil Sampling

Shaw conducted soil sampling activities at the WBG in 2004 to further evaluate surface soil and subsurface soil quality outside of the former burn area. Samples were collected from the pond access road, the drainage ditch on the northwest side of the pond access road, a drainage swale to the southwest of the burn area, and from the slope leading from the former burn area to the pond.

The investigation in the pond access road area included the advancement of 30 soil borings (SB1 through SB25, SB28, SB29, and SB32 through SB35). The borings were performed along the centerline and on each side of the dirt road. A total of 30 surface soil samples and 27 subsurface soil samples from these borings were field screened for lead using XRF. Thirteen of these samples [WBGSB43(0-0.5 ft bgs), WBGSB43(4-

5 ft bgs), WBGSB44(0-0.5), WBGSB44(1-2 ft bgs), WBGSB45(0-0.5 ft bgs), WBGSB45(4-5 ft bgs), WBGSB46(4-5 ft bgs), WBGSB47(5-6 ft bgs), WBGSB48(4-5 ft bgs), WBGSB49(1-2 ft bgs), WBGSB50(3-4 ft bgs), WBGSB51(3-4 ft bgs), and WBGSB52(3-4ft bgs)] were also submitted for laboratory analysis of PCBs and TAL inorganics. The subsurface soil samples corresponded to the layer of ashy material underlying the road as identified in previous investigations. The field screening results and laboratory analytical results from these samples are summarized in Table 9-13, and 9-14, respectively. The sample locations are depicted in Figures 9-2, 9-3, and 9-4. The results indicated:

XRF Field Screening Results. The XRF field screening results indicated that two of the surface soil samples (SB2 and SB34) and four of the subsurface soil samples (SB5, SB8, SB11, and SB14) contained lead at concentrations above the industrial and/or residential RSLs (see Table 9-13). These sample locations were all collected along the centerline of pond access road. The 28 other surface soil samples and 23 subsurface samples all had concentrations below applicable RSLs, which indicates that the extent of lead in the surface soils and subsurface soils is very limited.

PCBs. PCBs were not detected in any of the surface or subsurface soil samples (see Table 9-14).

TAL Inorganics. Several inorganics were detected in the surface and subsurface soil samples from the pond access road area (see Table 9-14). None of the detected constituents were at concentrations above background and industrial screening levels. However, aluminum was detected in one subsurface soil sample at a concentration above background levels and in the residential RSL. Iron was also detected in two subsurface soil samples at concentrations above background levels and the residential RSL.

Shaw's XRF field screening program also included the collection of 24 surface soil samples from the drainage ditch north of the pond access road, the sloped area between the former burn area and the pond, and a drainage swale leading into the pond. Seventeen of the field screened locations (WBGSB26 through WBGSB42) were also submitted for laboratory analysis of PCBs and TAL inorganics. In addition to TAL inorganics and PCBs, samples WBGSB26, WBGSB27, and WBGSB28, were analyzed for PAHs. The XRF field screening results and the laboratory analytical results from these samples are summarized in Tables 9-13 and 9-14. The XRF sample locations are depicted in Figure 9-4. The results indicated:

XRF Field Screening Results. The XRF Field screening results indicated that none of the 24 field screened surface soil samples contained lead at concentrations above the residential RSL (see Table 9-13). The XRF field screening results were typically biased high in comparison to the laboratory analyses where duplicate soil samples were collected.

PAHs. Thirteen PAH constituents were detected in the three soil samples submitted for laboratory analysis (see Table 9-14). The results indicated that benzo(a)pyrene was present at a concentration above the industrial RSL at sample location WBGSB27. This sample was located in the unlined drainage ditch located northwest of the pond access road. Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were also detected at concentrations above residential RSLs in the surface soil samples.

TAL Inorganics. Several inorganics were detected in the surface soil samples (see Table 9-14). However, none of the detected constituents were present at concentrations above applicable RSLs and background levels.

9.4.4.2 2004 Sediment Sampling

Shaw collected sediment samples from the unnamed pond for field screening and laboratory analysis to assess the extent of elevated inorganic constituent concentrations. The investigation activities focused on the northeastern side of the pond where lead and chromium had been detected at concentrations above industrial RSLs in 2002 sample location WBGSD10. Fourteen sediment samples (SD1 through SD14) were collected for field screening of lead using XRF. Ten samples (WBGSD16 through WBGSD25) were also submitted for laboratory analysis of PCBs and TAL inorganics. Sample location WBGSD16, which was collected where a drainage ditch enters the pond, was also analyzed for PAHs. XRF sample locations SD9 through SD14 correspond with lab sample locations WBGSD17 through WBGSD22, respectively. The XRF field screening results are presented in Table 9-13 and the laboratory analytical results are presented in Table 9-15. The sample locations are depicted in Figures 9-2 and 9-4. The results indicated the following.

XRF Field Screening Results. The XRF results indicated that 3 of the 14 sediment samples contained lead at concentrations above industrial RSLs. One additional sample also contained lead at a concentration above the residential RSL (see Table 9-13). All of the samples with concentrations above applicable screening levels were collected within a small area near the northern bank of the pond. The lead concentrations were below applicable screening levels in samples collected further from the shore of the pond.

PAHs. Several PAHs were detected in the WBGSD16 sediment sample collected where the drainage ditch enters the pond. However, benzo(a)anthracene, benzo(a)pyrene, and benzo(b)fluoranthene were the only constituents detected at concentrations above residential RSLs. No PAHs were detected above industrial RSLs.

PCBs. No PCBs were detected in any of the sediment samples during this event.

TAL Inorganics. Several inorganics were detected in all of the sediment samples. However, lead was the only constituent detected at a concentration above background levels and an applicable RSL (see Table 9-15). Lead was detected in one sediment sample (WBGSD17) at a concentration above the residential RSL. This sample was collected along the northern bank of the pond in the area where previous sampling had indicated elevated concentrations of lead and chromium. No inorganics were detected at concentrations above industrial RSLs.

9.4.4.3 2004 Fish Tissue/Bioaccumulation Study

Shaw performed electrofishing activities in the unnamed WBG pond in 2004. Fish species that were captured included: bluegill (*Lepomis macrochirus*), green sunfish (*Lepomis cyanellus*), common carp (*Cyprinus carpio*), and white sucker (*Catostomus commersoni*). Bluegills were the most abundant fish in the pond and were selected to represent water column dwelling fish in the pond. Only one common carp and one white sucker were collected and were used to represent bottom dwelling fish in the pond.

Seven bluegill ranging from 168 to 186 mm in length and 90 to 143 grams in weight were selected for whole body analysis(WBGTS01 through WBGTS07), while seven bluegill ranging from 190 to 222 mm in length and 140 to 233 grams in weight were selected for fillet analysis (WBGTS15 through WBGTS21). Due to the fact that only two bottom dwelling fish were collected, the single white sucker (410 mm in length and weighed 1 lb 15 oz) was selected for whole body analysis (WBGTS08) and the single common carp (670 mm in length and 10 lbs 8 oz) was selected for fillet analysis WBGTS22).

All fish tissue samples were sent to GPL Laboratories and analyzed for TCL PCBs, TAL inorganics, and percent lipids. Detected constituent are presented in Table 9-16.

Western Burning Ground

The results indicated that PCBs were not present in any of the fish tissue samples. Aluminum, barium, calcium, chromium, copper, iron, magnesium, manganese, mercury, potassium, sodium, and zinc were detected at varying concentrations in the samples (see Table 9-16). All of these constituents are naturally occurring in soils at the facility. Lead, which is the primary COPC in sediment at the WBG was not detected in any of the fish tissue samples.

9.4.5 Remedial Investigation, ARCADIS, 2008

In accordance with Remedial Investigation Work Plan Addendum 27 (ARCADIS 2008b), ARCADIS completed additional RI activities at the WBG in 2008 to finalize the characterization and delineation work at this site. This investigation included the following components:

- The pond was probed in several areas to determine the depth of the bottom sediments.
- Four sediment samples (WBG-SE001 through WBG-SE004) were collected from the area of the pond where elevated lead and chromium concentrations had been detected during the 2002 investigations. Three co-located surface water samples (WBG-SW002 through WBG-SW004) were also collected at these locations.
- Two co-located sediment (WBG-SE005 and WBG-SE006) and surface water (WBG-SW005 and WBG-SW006) samples were collected from the unnamed creek downgradient of the WBG pond to evaluate PAH detections that had been observed during previous sampling events.

The pond sediment gauging activities indicated that the sediments range in thickness from approximately 8 to 20 inches. Several large boulders are located in northeastern portion of the pond where the elevated lead concentration had been detected during previous sampling events.

The sediment samples collected from the pond (WBG-SE01 through WBG-SE04) were analyzed for lead by USEPA Method 6010B. The surface water samples were analyzed for TAL inorganics by USEPA Method 6010B. The laboratory analytical results for the sediment samples are summarized in Table 9-17 and the laboratory analytical reports are in Appendix F. The surface water analytical results are summarized in Table 9-18. The sample locations are depicted in Figure 9-2. The results of the sampling activities indicated:

- Lead concentrations ranged from 255 mg/kg (WBG-SE004) to 1,550 mg/kg (WBG-SE001) in the samples submitted for laboratory analysis. The lead concentrations at WBG-SE001 and WBG-SE003 were above the industrial RSL, while the concentration at WBGSE002 was only higher than the residential RSL (Table 9-17).
- The sediment sampling results confirm the presence of lead concentrations above applicable RSLs detected during previous sampling events.
- Lead concentrations in surface water ranged from 20.5 µg/l (WBG-SW002) to 106 µg/L (WBG-SW004) (see Table 9-18).

Two sediment (WBG-SE005 and WBG-SE006) and surface water samples (WBG-SW005 and WBG-SW006) were collected from the unnamed stream downgradient of the pond. The co-located WBG-SE005 and WBG-SW005 samples were collected approximately 120 ft downstream of the ponds earthen dam. The co-located WBG-SE006 and WBG-W006 samples were collected approximately 210 ft further downstream, near where the creek passes underneath a railroad bridge. The sediment and surface water samples were analyzed for PAHs by USEPA method 8270. The laboratory analytical results are summarized in Tables 9-17 and 9-18, respectively, and the laboratory analytical reports are in Appendix F. The sample locations are depicted in Figure 9-2. The results indicated the following:

- A total of 16 PAHs were detected in the two sediment samples from the creek. The detected constituents were all at concentrations below industrial RSLs. However, benzo(a)pyrene was detected above the residential RSL in sediment sample WBG-SE006 (see Table 9-17).
- No PAHs were detected at concentrations above tap water RSLs in either of the surface water samples. The PAHs that were detected were several orders of magnitude below applicable tap water RSLs (see Table 9-18).

9.5 Nature and Extent of Constituent Detections

The analytical results presented in the previous sections indicate that constituents have been detected at the WBG site as a result of historical burning ground operations. Site characterization activities performed at the WBG from 1997 through 1999 indicated the presence of an ashy layer of material throughout the burn area and elevated concentrations of inorganics and PAHs in burn area soils. A test pitting program completed in 1999 effectively removed all of the soils containing elevated constituent concentrations from the former burn area; therefore, the burn area is no longer a concern. Subsequent investigation activities at the site have focused on characterizing and delineating constituent detections outside of the burn area. Areas that have been investigated have included the access road on the northwest side of the burn area (underneath which an ashy layer of material has been identified); surface and subsurface soils located downgradient from the burn area; the berms surrounding the burn area; sediments and surface water in the unnamed pond; sediments and surface water in the unnamed creek downgradient of the pond; and a former transformer location.

9.5.1 Soil

Prior to the 1999 test pitting program, the soil sampling activities at the WBG primarily focused on the rectangular (170 ft by 100 ft) area where the former burning operations were conducted. The sampling and other investigation activities indicated that an ashy layer of material was present in surface and subsurface soils throughout the burn area as a result of the former burning operations. Analytical data from soil samples also indicated that dioxins/furans, PAHs, inorganics, and the PCB Aroclor 1254 were detected in soil within the burn area. Based on initial review of the data, lead appeared to be the primary concern within the burning area soil based on detections at concentrations above industrial RSLs. The burn area soils were removed during the 1999 test pitting program. A total of 43 confirmation samples were collected to verify that inorganics, PAHs, and dioxins/furans were no longer present at concentrations above applicable RSLs upon completion of the excavation activities. A site map depicting the confirmation soil sampling results is presented in Figures 9-5 and 9-6.

Outside of the burning area, one of the primary areas of investigation at the WBG has been the dirt access road which runs along the open side (northwestern side) of the former burn area. During the course of investigation at the site, an ashy layer of material was identified in the subsurface (approximately 2-4 ft bgs) under the road that was very similar to the ashy soils that had been present in the burn area. It is believed that this ashy layer of material was likely pushed out of the former burn area during regrading activities that would have been performed between burning events. This ashy layer was likely buried when the dirt road was constructed to the pond. The extent of the ashy layer was delineated by extensive soil boring activities completed in 1994 and 2004 and is confined to the subsurface soils underneath the road.

Surface soil and subsurface soil samples collected from the road area have been analyzed for SVOCs, PAHs, PCBs, and inorganics Samples have also been field screened for lead using XRF. The laboratory analytical results indicated that aluminum and iron were detected in isolated subsurface soil samples at concentrations above residential RSLs and slightly above the established background levels. Lead, which had been the main COPC in the former burial area was present in surface and subsurface soils in the access road area at concentrations above established background concentrations but below residential RSLs. XRF field screening results also indicated that lead concentrations were below screening levels in 53 of the 58 samples; however, the XRF results did indicate that lead was present at concentrations above industrial RSLs in 3 of the 58 samples and above residential RSLs in 2 others. SVOCs/PAHs and PCBs were not detected in surface or subsurface soils in the road area.

Six soil samples (WBGSB6 through WBGSB11) were collected from the berms surrounding the burn area in 1999. The samples were analyzed for TCL VOCs, TCL SVOCs, PAHs, explosives, TAL inorganics and pH. The results indicated that inorganics concentrations within the berm were comparable to the established background levels for the facility and that no other constituents were detected above applicable RSLs. These results suggest that ash from the burning activities was not mixed with the soil in the berm and that the berm was likely constructed from native soil in the area prior to the initiation of burning activities at the WBG.

Surface and subsurface soil samples were collected downgradient (northwest, west, and south) of the burning ground and road to evaluate the potential for constituents to have migrated outside the burn area. Samples were analyzed for VOCs, SVOCs/PAHs, pesticides, herbicides, dioxins/furans, explosives, and inorganics. The results from these areas indicated:

- No VOCs were detected at concentrations above applicable industrial or residential RSLs.

- Seventeen different PAHs were detected in surface and subsurface soil outside of the former burn area. Benzo(a)pyrene was detected at a concentration above the industrial RSL in two surface soil samples (WBGSB24 and WBGSB25) and one subsurface soil sample [WSBGSB22(2-4 ft bgs]. Benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were also detected in these samples at concentrations above residential RSLs. The WBGSB22 sample location is at the end of the dirt pond access road, and the WBGSB24 and WBGSB25 sample locations are in a small drainage pathway located west, and downslope, from the former burn area. This area receives runoff from the former burn area and from the surrounding RFAAP-NRU roads and flows into the pond.

- No PCBs were detected in the soil sample collected at the former transformer location; however, the PCB Aroclor 1254 was detected in one subsurface soil sample [WBGSB22(2-4 ft bgs)] located at the end of the pond access road. This constituent was not detected in surface soil or deeper (6-8 ft bgs) samples collected at the WBGSB22 boring location. PCBs were not detected in any other samples at the site. Therefore, the one detection appears to be isolated.

- Four herbicides (2,4,5-TP, 2,4-D, dalapon, and MCPP) and two pesticides (4,4'-DDD, and dieldrin) were detected at low concentrations in four surface soil samples (WBGSB22 through WBGSB25). The detected concentrations were several orders of magnitude below residential RSLs.

- The dioxin 1,2,3,7,8 PeCDD was detected in one subsurface soil sample [WBGSB22(2-4 ft bgs)] at a concentration above the residential RSL. Several other dioxins/furans were detected in surface and subsurface samples, but the concentrations were all lower than residential RSLs.

- Despite the fact that the former burning ground operations were used to decontaminate and dispose of materials that had been in contact in explosive/energetic compounds, explosives were not found to be a concern at the site. Only one explosive compound was ever detected during the course of sampling at a single location. Penterythritol tetranitrate was detected at a concentration of 0.11 mg/kg at surface soil at WBGSB24.

A site map is presented in Figure 9-7 that displays inorganic constituents detected in soil outside of the burn area at concentrations above background levels. Figure 9-8 displays the organic constituents detected in soil outside of the burn area.

9.5.2 Sediment

The unnamed pond located at the WBG was another area of focus during the environmental investigations at the site due to the potential for affected media (i.e., soils and ashy material) to have been transported from the former burn area. A total of 26 sediment samples were collected from the pond between 1997 and 2008. These samples were primarily collected along the northern side of the pond, closest to the former burning area and in areas that appeared to be in preferential flow paths from the surrounding area. The laboratory analytes varied between the sampling events but have included VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides, explosives, dioxins/furans, and inorganics. The results indicated the following:

- Five different VOCs were detected in pond sediment samples (2-butanone, acetone, carbon disulfide, methylene chloride, and toluene). The detections are generally attributed to laboratory instrument contamination. The detected concentrations were all several orders of magnitude below applicable residential RSLs.

- The PAH benzo(a)pyrene was detected above the residential RSL in 3 pond sediment samples (SD-01, WBGSD12, and WGSD16). Benzo(a)anthracene and benzo(b)fluoranthene were also detected at WBGSD16 at concentrations above residential RSLs. Sample locations WBGSD12 and WBGSD16 are located near where a surface water drainage ditch enters the pond. Sample location SD-01 is located at the head waters of the pond (near Wiggins Spring). Surface water runoff from the surrounding area also enters the pond near SD-01.

- PCBs were not detected in the pond sediment samples.

- Seven different pesticides were detected in one pond sediment sample (WBGSD10). However, the detected concentrations were several orders of magnitude below residential RSLs.

- No herbicides were detected in pond sediments.

- The explosives nitroglycerine and 1,3,5-trinitrobenzene were detected in one sediment sample collected in the vicinity of where a drainage feature enters the pond (WBGSD12). The concentration of nitroglycerine was above the residential RSL. Explosives were not detected in any other sediment samples from the pond.

- Several dioxins/furans were detected in pond sediment samples; however, all detected constituents were below residential RSLs.

- Lead was detected in pond sediments at concentrations ranging from 20.6 mg/kg to 109,000 mg/kg. The lead concentrations were above the industrial RSL in 4 of the 26 sediment samples, and above the residential RSL in 2 other samples. The samples with lead concentrations above the RSLs (WBGSD5,

WBGSD10, WBGSD17, WBG-SE001, WBG-SE002, and WBG-SE003) were generally confined to a 2,100 ft^2 area along the north-central bank of the pond in an area that may have been a preferential flow path before the road was constructed. Several large boulders are present in the pond in this area Delineation sampling using both laboratory analytical samples and XRF field screening confirmed that lead concentrations decrease with distance from the northern edge of the pond.

- Chromium and cobalt were the only other inorganics detected at concentrations above established background levels and applicable RSLs Chromium was detected in five of 24 samples at concentrations above background and residential RSLs; although the majority of the detected concentrations were only slightly above background. The highest detected concentration of chromium (15,400 mg/kg) occurred at sample location WBGSD10, which also had the highest concentration of lead. Cobalt was also detected at a concentration above background and the industrial RSL at WBGSD10. The elevated chromium and cobalt detections were confined to the same area where lead was detected above the RSLs.

A gauging program conducted in 2008 indicated that the pond sediments range in thickness from 8 to 20 inches.

A total of six sediment sample (WBGSD1, WBGSD08, WBGSD09, WBGSD13, WBG-SE005, and WBG-SE006) have been collected from the stream downgradient of the pond's earthen dam. This stream receives outfall water from the pond. The analytical results from the various sampling events indicated the following:

- Benzo(a)pyrene, benzo(a)anthracene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene were detected above the industrial RSL at sample location WBGSD09 in 2002. This sample is located approximately 300 ft downstream from the ponds earthen dam, near where the stream passes under a railroad bridge. A second sample (WBG-SE006) was collected in 2008 near the WBGSD09 sample location. This sample indicated that only benzo(a)pyrene was present at a concentration above residential RSLs. No other PAHs were detected above applicable RSLs at WBG-SE006. Sediment samples collected upstream have not had PAH detections above applicable RSLs.

- Arsenic and iron were detected at sample location WBGSD13 in 2002 at concentrations above background levels and RSLs.. These constituents were within background levels in the other sediment samples from the stream.

- Pesticides, herbicides, and dioxins/furans detected in sediment samples from the stream were below applicable RSLs.

One sediment sample (WBSD14) was collected from the unnamed creek that flows through the southwest portion of the RFAAP-NRU. This sample was collected upstream of where the unnamed creek first flows onto the installation, prior to the confluence with the tributary flowing out of the WBG pond. This sample location is outside the range of influence of the WBG. The results from this sample indicated that several PAHs were present at concentrations above applicable RSLs [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene]. Pesticides and herbicides were also detected in this sample; albeit at concentrations below applicable RSLs.

A sediment sample was collected from a surface water drainage feature on the western side of the pond (WBGSD15) to identify whether or not other sources were present for the constituents detected in the pond. The results from this sample indicated the presence of pesticides, PAHs, and inorganics, but at concentrations below applicable RSLs and/or background levels.

A site map depicting the inorganic constituents detected in sediment samples during the WBG investigation is presented in Figure 9-9. Figure 9-10 displays the organic constituents that were detected in the sediment samples.

9.5.3 Surface Water

A total of 20 surface water samples were collected during the course of the WBG investigation. In general, the samples were collected in conjunction with the sediment samples discussed earlier. Surface water samples were collected from the WBG pond, the tributary to the unnamed creek that accepts the outfall from the pond, the unnamed creek upstream of the confluence with the WBG stream, and a drainage feature located to the west of the pond. The results indicated the following:

- The herbicide MCPP was detected in surface water sample WBGSW08 at a concentration of 54.1 µg/L which is above the tap water RSL of 37 µg/L. This sample was located in the stream that accepts the outfall from the WBG pond. This constituent was also detected in the sediment sample at this location (WBGSD08), but was not present in pond sediments or surface water.

- The pesticide dieldrin was detected in two samples (WBGSW08 and WBGSW14) at concentrations above tap water RSLs. Sample location WBGSW14 was in the unnamed stream that flows through the RFAAP-NRU (, upstream of where the stream first enters the RFAAP-NRU installation boundary and prior to the confluence with the stream from the WBG. This indicates the possible presence of a dieldrin source somewhere off of the facility.

- Perchlorate and tetrachloroethene were also detected in the WBGSW14 sample at concentrations above tap water RSLs. This constituent was not detected in any other surface water, sediment, or soil samples at the WBG.

- Lead was detected at elevated concentrations (i.e., above 5.0 µg/L) in four surface water samples from the pond (WBGSD10, WBG-SW002, WBG-SW003, and WBG-SW004). These samples were all located in the area of the pond where the elevated lead concentrations were detected in sediment.

- Arsenic, iron, manganese, and thallium were each detected in one surface water sample at concentrations above tap water RSLs.

A site map depicting the inorganic constituents detected in surface water is presented as Figure 9-11. Figure 9-12 presents the organic constituents detected at the surface water sample locations.

9.6 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. Risk assessment datasets for soil, sediment, surface water, and fish tissue for the WBG were prepared then summarized and statistically analyzed per methods described in Appendix A. Risk assessment dataset summaries were prepared highlighting the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPCs. To prepare a dataset representing what site conditions might be should the pond at the WBG be drained, data from soils and sediment were combined to calculate an EPC representing the merged samples. This information is presented in Tables 9-19 through 9-25.

Data for fish fillets and whole body fish (Tables 9-24 and 9-25, respectively) were each presented for use in the risk assessment datasets. The fish filets data were used in the HHRA and the whole body data were used in the ERA.

9.7 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with constituents detected in soil, sediment, surface water, and fish tissue samples collected at the WBG. The risk assessment approach follows the Radford Army Ammunition Plant Final Master Work Plan (URS 2003).

This section summarizes the occurrence of constituents in each medium and identifies COPCs at the WBG for the human health risk assessment; identifies the potential human exposure scenarios relevant to the WBG; and presents the estimated human health risks associated with the identified COPCs and the relevant human exposure scenarios at the WBG. Methodologies for data summary and selection of COPCs, exposure assessment, and toxicity assessment for the HHRA were presented in Appendix A.

9.7.1 Selection of Constituents of Potential Concern

This section discusses the selection of COPCs for the HHRA for each medium at the WBG.

9.7.1.1 Surface Soil

Surface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 9-26 presents the selection of surface soil COPCs for the HHRA. As summarized in Table 9-26, 14 constituents were identified as COPCs in surface soil:

- **VOCs:** d-limonene;
- **SVOCs:** carbazole;

- **Explosive:** pentaerythritol tetranitrate;
- **PAHs:** benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene; and
- **Inorganics:** antimony, arsenic, copper, iron, lead, and zinc.

9.7.1.2 Combined Surface and Subsurface Soil

Combined surface and subsurface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 9-27 presents the selection of combined surface and subsurface soil COPCs for the HHRA. As summarized in Table 9-27, 17 constituents were identified as COPCs in combined surface and subsurface soil:

- **VOCs:** d-limonene;
- **SVOCs:** carbazole;
- **Dioxin/Furans:** 1,2,3,7,8-PeCDD;
- **Explosive:** pentaerythritol tetranitrate;
- **PAHs:** benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene;
- **PCB:** Aroclor 1254; and
- **Inorganics:** aluminum, antimony, arsenic, copper, iron, lead, and zinc.

9.7.1.3 Sediment

Sediment COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table 9-28 presents the selection of sediment COPCs for the HHRA. As summarized in Table 9-28, 17 constituents were identified as COPCs in sediment:

- **SVOCs:** carbazole;

- **Explosives:** nitroglycerine;

- **PAHs:** benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene; and

- **Inorganics:** aluminum, arsenic, chromium, cobalt, iron, lead, manganese, thallium, vanadium, and zinc.

9.7.1.4 Surface Water

Surface water COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for tap water. Table 9-29 presents the selection of surface water COPCs for the HHRA. As summarized in Table 9-29, 10 constituents were identified as COPCs in surface water:

- **VOCs:** chloroform and tetrachloroethene;

- **Herbicides:** MCPP;

- **Pesticides:** dieldrin; and

- **Inorganics:** arsenic, iron, lead, manganese, thallium, and vanadium.

9.7.1.5 Fish Tissue

Fish tissue COPCs were to be selected by comparison to acceptable consumption levels (USEPA, 2000); however, none of the constituents detected had identified acceptable consumption levels. As a result, all constituents detected with the exception of essential nutrients were selected as fish tissue COPCs. Table 9-30 presents the selection fish tissue COPCs for the HHRA. As a conservative measure, maximum concentrations were used as EPCs for fish ingestion. As summarized in Table 9-30, the following constituents were identified as COPCs in fish tissue for the HHRA: barium; chromium; copper; iron; manganese; mercury; and zinc.

9.7.2 Human Health Risk Characterization

The EPCs for the WBG are summarized in Table 9-31.

Exposure to soil, sediment, and surface water COPCs was evaluated for direct contact. Ingestion of fish caught at the WBG was evaluated as well. VOCs identified as COPCs in the WBG were also evaluated for inhalation via vapor migration into buildings. One VOC, d-limonene, was identified as a soil COPC at the WBG. This COPC does not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area.

The excess lifetime cancer risks and non-cancer hazards and the estimated blood lead levels for each potentially exposed receptor included in the risk assessment for the WBG are presented in Appendix A and are summarized in Tables 9-32 and 9-33 and in the tables below. Results are discussed by receptor in following subsections. In addition to the site worker, construction worker, and resident scenarios evaluated for all areas, two additional sets of exposures were evaluated for the WBG area: exposures to participants (adults and children) who might be exposed to sediment via wading during the annual two-day fish rodeo; and exposures to site workers, hypothetical construction workers, and hypothetical future residents (adults and children) for whom soil exposure would encompass both current soil and sediment in the event that the pond at the WBG were drained.

Summary of Calculated ELCRs and HIs for Receptor Exposure Scenarios

RECEPTOR/ EXPOSURE MEDIUM - SCENARIO	ELCR	HI
Site Worker		
Surface Soil - Direct Contact	1E-05	0.1
Sediment – Wading	2E-06	0.1
Surface Water - Wading	3E-06	0.2
TOTAL SITE RISKS (Site Worker):	**1E-05**	**0.4**
Hypothetical Future Construction Worker		
Combined Surface and Subsurface Soil - Direct Contact	5E-07	0.5
TOTAL SITE RISKS (Construction Worker):	**5E-07**	**0.5**
Hypothetical Future Adult Resident		
Combined Surface and Subsurface Soil - Direct Contact		0.2
Sediment – Wading		0.2
Surface Water - Wading		0.04
Fish Consumption		0.3
TOTAL SITE RISKS (Adult Resident):		**0.8**
Hypothetical Future Child Resident		
Combined Surface and Subsurface Soil - Direct Contact		2
Sediment – Wading		2
Surface Water - Wading		0.1
Fish Consumption		1
TOTAL SITE RISKS (Child Resident):		**6**

Western Burning Ground

Summary of Calculated ELCRs and HIs for Receptor Exposure Scenarios (continued)

RECEPTOR/ EXPOSURE MEDIUM - SCENARIO	ELCR	HI
Hypothetical Future Resident (Adult and Child)		
Combined Surface and Subsurface Soil - Direct Contact	4E-05	
Sediment – Wading	1E-05	
Surface Water - Wading	1E-06	
Fish Consumption	NA	
TOTAL SITE RISKS (Resident):	**5E-05**	
Hypothetical Future Adult Resident (Fishing Rodeo)		
Sediment - Wading	2E-07	0.009
Hypothetical Future Child Resident (Fishing Rodeo)		
Sediment - Wading	2E-07	0.08
Site Worker (Drained Pond)		
Combined Surface Soil and Sediment	1E-05	0.5
Hypothetical Future Construction Worker (Drained Pond)		
Combined Surface Soil and Sediment	6E-07	0.8
Hypothetical Future Adult Resident (Drained Pond)		
Combined Surface Soil and Sediment	1E-05	0.7
Hypothetical Future Child Resident (Drained Pond)		
Combined Surface Soil and Sediment	3E-05	6

Summary of Estimated Blood Lead Levels for Receptor Exposure Scenarios

RECEPTOR	Estimated Blood Lead Level (µg/dL)		
	Adult	**Child**	**Fetus**
	50th percentile	**Range**	**95th percentile**
SOIL			
Site Worker	2.0	–	7
Hypothetical Future Construction Worker	2.0	–	7
SOIL AND SEDIMENT			
Hypothetical Future Child Resident	–	2.9 – 5.5	–
Hypothetical Future Adult Resident	2.8	–	10

9.7.2.1 Site Worker

A current or future site worker could be present at the WBG area, and could be exposed to surface soil, sediment, and surface water. The ELCR and non-cancer hazard index for site worker exposure to each medium are presented in Appendix A and are summarized in Table 9-32. As presented in the table above, the ELCRs for surface soil, sediment, and surface water are all within the USEPA target risk range, and the HIs for each medium are all below the benchmark value of 1.

The total cumulative ELCR for site workers exposed to surface soil, sediment, and surface water at the WBG is 1×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.4, which is less than the benchmark of 1.

The 50th percentile blood lead level estimates for the site worker receptor from exposure to lead in soil was calculated to be 2 µg/dL, and the 95th percentile blood lead levels estimated for the fetus of the receptor was at 7 µg/dL. Both of these estimated blood lead levels are below the benchmark of 10 µg/dL.

9.7.2.2 Hypothetical Future Construction Worker

A hypothetical future construction worker could be present at the WBG area, and could be exposed to combined surface and subsurface soil. The ELCR and non-cancer hazard index for hypothetical future construction worker exposure to soil are presented in Appendix A and are summarized in Table 9-32. As presented in the table above, the ELCR for combined surface and subsurface soil is below the USEPA target risk range, and the HI is below the benchmark value of 1.

The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the WBG was 5×10^{-7}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 0.5, which is less than the benchmark of 1. The 50th percentile blood lead level estimates for the site worker receptor from exposure to lead in soil was calculated to be 2 µg/dL, and the 95th percentile blood lead levels estimated for the fetus of the receptor was at 7 µg/dL. Both of these estimated blood lead levels are below the benchmark of 10 µg/dL.

9.7.2.3 Hypothetical Future Residents

A hypothetical future resident could be present at the WBG area, and could be exposed to combined surface and subsurface soil, sediment, or surface water. The ELCR and non-cancer hazard index for hypothetical future resident exposure to each medium are presented in Appendix A, and are summarized in Table 9-32.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, surface water, and ingestion of fish at the WBG is 5×10^{-5} , which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}.

The total cumulative HI for hypothetical future adult residents is 0.8, which is less than the benchmark of 1.

The total cumulative HI for hypothetical future child residents is 6, which is above the benchmark of 1. When the HI for combined surface and subsurface soil is segregated into target site and critical effects, none of the hazards are above the benchmark of 1. When the HI for sediment is segregated into target site and critical effects, only the HI for chromium (which is based on a toxicological study in which no effects were observed) exceeded the benchmark of 1.

Lead was a COPC in both soil and sediments at the WBG. Exposure to the sediments is intermittent, but exposure to sediments needs to be combined with the exposure to soil to calculate a cumulative exposure to lead for each receptor. As a result, a time-weighted average lead concentration was calculated assuming 350 days/year exposure to lead in soil and 48 days/year exposure to lead in sediments. This resulted in an EPC of 623 mg/kg of lead. The 50^{th} percentile blood lead level estimates for the adult resident receptor from exposure to lead in soil and sediment was calculated to be 2.8 µg/dL and the 95^{th} percentile fetal blood lead level was 10 µg/dL. The adult level is well below the benchmark and the fetal level is at the benchmark.

The IEUBK model for childhood exposure to lead includes the contribution of exposure to lead in dust. The time-weighted exposure point concentration included both soil and sediment contributions. However, soil is more likely to contribute to dust exposure than would sediment. As a result, the dust concentration was based on the soil EPC and was set at 70 mg/kg for the entire exposure period. The blood lead level estimates for the hypothetical child resident receptor from exposure to lead in soil and sediment were evaluated and the predicted annual blood lead levels ranged from 2.9 µg/dL to 5.5 µg/dL. Exposure of a child over a seven year period resulted in a geometric mean blood lead concentration of 4.26 µg/dL, below the 10 µg/dL benchmark, and a prediction of 3 percent of the population having blood lead concentrations above the 10 µg/dL benchmark.

9.7.2.4 Fish Rodeo Participants

Potential risks were evaluated for participants in the semi-annual fishing rodeo held at the WBG pond. The fishing rodeo would occur two days per year. Individuals who catch fish would be allowed to retain them. However, as the pond would be stocked with fish just before the rodeo begins, it is not likely that they would accumulate any COPCs during that time. Thus, the only potential risk to adults and children who participate in the rodeo would be through direct contact with sediments. Accordingly, ELCRs and HIs for this potential sediment exposure were calculated by using exposure factors for the residential scenario modified to replace the exposure frequency from 48 days/year to 2 days/year. The ELCRs and non-cancer hazard index for hypothetical adult and child participants in the fish rodeo are presented in Appendix A.

The ELCR for the hypothetical fish rodeo participants exposed to sediments at the WBG was 4×10^{-7} which is below the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for adult participants was 0.009, which is substantially less than the benchmark of 1. The total cumulative HI for child participants was 0.08, which is also less than the benchmark.

9.7.2.5 Site Worker, Hypothetical Future Construction Worker, and Hypothetical Resident – Drained Pond

The HHRA for the WBG area also estimated hypothetical risks to current and future site workers, hypothetical future construction workers, and hypothetical future residents if the pond is drained in the future, which could result in current sediments becoming part of the soil to which these residents might be exposed. To complete this evaluation, the EPCs were modified to represent combined soil and sediment samples. Exposure factor values were otherwise identical to those used in the evaluation of exposure to soils for these receptors. If the pond were to be drained, wading and fishing would no longer be possible, so exposures by those pathways were not included when characterizing risks if the pond were drained in the future. The ELCRs and HIs for potential receptors under a future drained pond scenario are presented in Appendix A.

The total cumulative ELCR for future site workers exposed to combined surface soil, subsurface soil, and current sediment at the WBG was 1×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical site construction workers is 0.5, which is less than the benchmark of 1.

The total cumulative ELCR for hypothetical future construction workers exposed to combined surface soil, subsurface soil, and current sediment at the WBG was 6×10^{-7}, which is below the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 0.8, which is less than the benchmark of 1.

The total cumulative ELCR for hypothetical future residents exposed to combined surface soil, subsurface soil, and current sediment at the WBG was 5×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical adult residents is 0.7, which is below the benchmark. The total cumulative HI for hypothetical child residents is 6, which is greater than the benchmark value of 1. When the HI is segregated into target site and critical effects, only the HI for chromium (which is based on a toxicological study in which no effects were observed) exceeded the benchmark of 1.

These results indicate that risks to future site workers, hypothetical future construction workers, or hypothetical future adult residents would be acceptable if the pond at the WBG were drained in the future, thereby adding current sediment to the material to which direct contact soil exposures might occur. There is a slightly elevated potential hazard to child residentsassociated with the presence of chromium in soil.

9.7.3 Human Health Risk Summary

Table 9-32 summarizes the calculated cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the WBG. The total ELCR values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below or within the benchmark range of 10^{-6} to 10^{-4} for cancer risk. Under the current industrial land use, the total HI values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below the benchmark of 1 for non-cancer hazard.

Under the future hypothetical residential scenario, the ELCR values for the resident are within the generally accepted target risk range. However, the target organ specific HI for the child resident exposure to sediment was greater than 1, due to the presence of chromium.

Exposure to lead in soil by site workers or construction workers would not result in a predicted blood lead level greater than the benchmark of 10 µg/dL. Exposure of residents to lead in soil and sediment, however, resulted in a predicted fetal blood lead level above the benchmark. Exposure to lead in soil and sediment by a child resulted in a geometric mean blood lead level below the benchmark, but also a prediction of 3 percent of the population with blood lead levels above the benchmark.

Based on the results of the risk assessment, it is unlikely that industrial use of the property would result in adverse health effects. Likewise, no adverse effects would be expected for participants in the semi-annual fish rodeo. For the residential exposure scenarios, exposure to lead in sediments may pose an adverse health effect. Also, exposure to chromium in sediments may pose a slightly elevated hazard to children wading in surface water and sediments. Several (four) of the chromium detections in sediment were greater than the background chromium soil range. The maximum chromium sediment concentration of 15,400 mg/kg is well above the background range.

If the pond were drained in the future, it is unlikely that industrial or residential use of the property would result in adverse health effects with the exception of a slightly elevated hazard to children resulting from direct contact exposures to existing soils combined with sediment that would become soil.

9.8 Ecological Risk Assessment

The purpose of the ERA is to evaluate whether ecological receptors may be adversely impacted by exposure to site-related constituents detected in surface soil, sediment, surface water, and fish tissue at the WBG. This section summarizes the occurrence of constituents in each medium and identifies COPECs at the WBG for the ecological risk assessment; identifies the potential ecological exposure scenarios relevant to the WBG; and presents the estimated ecological risks associated with the identified COPECs and the relevant ecological exposure scenarios at the WBG. Methodologies for data summary and selection of COPECs, exposure assessment, and toxicity assessment for the ERA were presented in Appendix A.

9.8.1 Selection of Constituent of Potential Ecological Concern

This section discusses the selection of COPECs for each medium. Risks to ecological receptors are calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the hazard quotient (HQ), is a highly conservative surrogate for the assessment endpoints identified in Appendix A. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse ecological effects are unlikely (USEPA 1997c). HQs greater than 1 indicate that further evaluation is warranted. Therefore, the constituents with HQs greater than 1 or bioaccumulative are carried forward as COPECs into the BERA. Maximum HQs greater than 1 for the WBG area are summarized in the subsections below.

9.8.1.1 Surface Soil

Surface soil COPECs were selected by comparing the analytical data with USEPA (2005b) EcoSSLs, USEPA (2003e) Region 5 ESLs, and ORNL values (Efroymson et al. 1997a,b) for surface soil. Table 9-34 presents the selection of surface soil COPECs for the ERA. As summarized in Table 9-34, 38 constituents were identified as COPECs in surface soil:

- **VOCs:** d-limonene and p-isopropyltoluene;
- **SVOCs:** carbazole and dibenzofuran;
- **Dioxin/furans:** dioxin toxicity equivalent;
- **Explosive:** pentaerythritol tetranitrate;
- **Herbicides:** dalapon and MCPP;
- **Pesticides:** 4,4’-DDD and dieldrin;
- **PCBs:** Aroclor 1254;
- **PAHs:** acenaphthene, acenaphthylene, anthracene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, phenanthrene, and pyrene
- **Inorganics:** antimony, arsenic, barium, cadmium, chromium, copper, iron, lead, mercury, selenium, silver, and zinc.

9.8.1.2 Sediment

Sediment COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Sediment Screening Levels; ORNL values (Jones et al. 1997); and USEPA (2003e) Region 5 Ecological Screening Levels for sediment. Table 9-35 presents the selection of sediment COPECs for the ERA. As summarized in Table 9-35, 55 constituents were identified as COPECs in sediment:

- **VOCs:** 2-butanone, acetone, and carbon disulfide;
- **SVOCs:** 1,2,4-trichlorobenzene, 1,4-dichlorobenzene, 4-methylphenol, bis[2-ethylhexyl]phthalate, and carbazole; ,
- **Dioxin/furans:** dioxin toxicity equivalent;
- **Explosives:** 1,3,5-trinitrobenzene and nitroglycerine;
- **Herbicides:** 2,4-D, dicamba, and MCPP;
- **Pesticides:** 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, delta-BHC, alpha-chlordane, dieldrin, endosulfan II, and methoxyclor;
- **PAHs:** 2-methylnaphthalene, acenaphthene, acenaphthylene, anthracene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, phenanthrene, and pyrene; and
- **Inorganics:** antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, nickel, selenium, silver, thallium, vanadium, and zinc.

9.8.1.3 Surface Water

Surface water COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Surface Water Screening Levels; ORNL values (Suter and Tsao 1996); USEPA (2003e) Region 5 Ecological Screening Levels; and USEPA (2008e) Ambient Water Quality Criteria for surface water. Table 9-36 presents the selection of surface water COPECs for the ERA. As summarized in Table 9-36, 25 constituents were identified as COPECs in surface water:

- **VOCs:** chloroform;
- **SVOCs:** 1,2-dichlorobenzene; 1,3-dichlorobenzene; 1,4-dichlorobenzene
- **Herbicides:** MCPP;
- **Dioxin/furans:** dioxin toxicity equivalent;
- **Pesticides:** dieldrin

  PAHs: anthracene, acenaphthene, fluorene, and phenanthrene;
- **Inorganics:** aluminum, arsenic, barium, beryllium, copper, iron, lead, nickel, manganese, silver, selenium, thallium, zinc, and vanadium.

One spring sample (WBG_SPRING001) was also evaluated for surface water COPECs by comparing the analytical data with background spring data as well as ESLs. As shown in the table below, one PAH and six inorganics were detected in the spring sample. Four of the inorganics are vital electrolytes and/or essential nutrients (calcium, magnesium, potassium, and sodium) and therefore were identified as non-toxic and not evaluated further. The remaining constituents detected in the spring sample were within or below the background concentrations or were below the corresponding ESL, and as a result, were not evaluated further.

Detected Constituents in Spring Sample – Rail Yard

Constituent	ESL (µg/L)	Background Spring Data NSPRING003 09/24/08	NSPRING004 09/24/08	WBG_SPRING001 09/24/08	Does Max Exceed ESL or BKG?
PAHs					
Naphthalene	**1.1**	<0.092	<0.092	0.032	no

Zinc	**120**	9	7	9.3	no

µg/L Micrograms per liter. NT Non-toxic.

9.8.2 Summary of Selected Constituents of Potential Ecological Concern

Thirty-eight constituents were selected as COPECs in surface soil, fifty-five constituents were selected as COPECs in sediment, and twenty-five constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was bioaccumulative, or an HQ couldn't be calculated because an ESL was not available.

9.8.3 Refinement of Risk Calculations for Direct Contact COPECs

The list of COPECs identified in the BERA was reevaluated by calculating refined HQs. The refined HQs were calculated for the COPECs identified in the SLERA using refined EPCs. Constituents identified as COPECs in the BERA that were bioaccumulative were carried forward into food chain models. The results of the recalculation of the HQs for the WBG are summarized in the subsections below.

9.8.3.1 Surface Soil

Thirty-eight COPECs in surface soil were carried forward into the BERA. When refined EPCs were compared with the ESLs, six constituents (PCDDs/PCDFs, antimony, chromium, copper, lead, and zinc) had a refined HQ greater than 1. In addition, ESLs were not available for 9 other constituents (d-limonene, p-isopropyltoluene, carbazole, dibenzofuran, pentaerythritol tetranitrate, dalapon, MCPP, Aroclor 1254, and iron). The BERA results for surface soil COPECs at the WBG are presented in Table 9-37 and are discussed in Appendix A.

Of the COPECs, 26 were evaluated in the terrestrial food chain model.

9.8.3.2 Sediment

Fifty-five COPECs in sediment were carried forward into the BERA. When refined EPCs were compared with the ESLs, 27 constituents [2-butanone, acetone, carbon disulfide, 4-methylphenol, dioxin TEQ, 2,4-D, dieldrin, 2-methylnaphthalene, acenaphthene, acenaphthylene, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(g,h,i)perylene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, pyrene, chromium, copper, iron, lead, manganese, silver, and zinc], had a refined HQ greater than 1. In addition, ESLs were not available for nine other constituents [carbazole, 1,3,5-trinitrobenzene, nitroglycerine, dicamba, MCPP, barium, beryllium, thallium, and vanadium]. The BERA results for sediment COPECs at the WBG are presented in Table 9-38 and are discussed in Appendix A.

Thirty-four of the constituents in sediment were identified as bioaccumulaive and evaluated in the aquatic food chain model.

9.8.3.3 Surface Water

Twenty-five COPECs in surface water were carried forward into the BERA. When refined EPCs were compared with the ESLs, 10 constituents (anthracene, aluminum, arsenic, barium, beryllium, copper, iron, lead, manganese, and thallium) had a refined HQ greater than 1. In addition, an ESL was not available for MCPP. The BERA results for surface water COPECs at the WBG are presented in Table 9-39 and are discussed in Appendix A.

Twelve surface water COPECs were identified as bioaccumulative and evaluated in the aquatic food chain model.

9.8.4 Refinement of Assessment and Measurement Endpoints for Bioaccumulative COPECs

Food chain modeling was conducted at the WBG in order to evaluate the potential ecological effects of the bioaccumulative COPEC in soil, sediment, and surface water on the receptors identified in Appendix A. COPECs identified in soil were evaluated in the terrestrial food chain, and COPECs identified in sediment and surface water were evaluated in the aquatic food chain. The results for both the maximum and refined scenarios of these models are presented in Appendix A, and the results of each of the refined scenarios are summarized in the subsections below.

9.8.4.1 Terrestrial Food chain Model

As summarized in Table 9-40, the refined scenario NOAEL HQs and LOAEL HQs for the short-tailed shrew were less than 1 for all of the bioaccumulative COPECs, with the exception of dibenzo(a,h)anthracene and zinc. The dibenzo(a,h)anthracene NOAEL HQ was 4 and the LOAEL HQ was 0.4 and the zinc NOAEL HQ was 8 and the LOAEL was 0.8. The NOAEL is a very conservative screening criterion while the LOAEL indicates a concentration above which adverse impacts to individual mammals and birds may occur. For the American robin, the refined scenario NOAEL HQs and LOAEL HQs were less than 1 for all of the bioaccumulative COPECs, with the exception of lead; however, the NOAEL is a very conservative toxicity screening value, and the HQs for the more realistic LOAEL are less than 1. These results indicate that individual short-tailed shrews and American robins (or other insectivorous mammals and birds) exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of terrestrial food chain modeling HQs and consideration of the limited spatial extent of impacted soils, adverse effects are not expected for short-tailed shrews (and other insectivorous mammals) and American robins (and other insectivorous birds) populations exposed to bioaccumulative COPECs in soil at the WBG.

9.8.4.2 Aquatic Food chain Model

As summarized in Table 9-41, the refined scenario NOAEL HQs and LOAEL HQs for both the mink and the great blue heron were less than or equal to 1 for all of the bioaccumulative COPECs identified in sediment and/or surface water indicating no adverse impacts to mink (or other piscivorous mammals) or heron (or other piscivorous birds) at a population level. .

9.8.5 Ecological Risk Summary

Screening-level and baseline risk assessments were completed for the WBG. After the SLERA, 38 constituents were selected as COPECs in surface soil, 55constituents were selected as COPECs in sediment, and 25 constituents were selected as COPECs in surface water because the HQs were greater than 1 or an HQ could not be calculated because an ESL was not available. For the BERA, 36 constituents in surface soil, 52 constituents in sediment, and 23 constituents in surface water were retained because the HQs were greater than 1, the chemical was bioaccumulative, or an HQ could not be calculated because an ESL was not available. Food chain modeling was evaluated for those constituents identified as bioaccumulative.

Tables 9-40 and 9-41 summarize the constituents in surface soil, sediment, and surface water carried through the BERA and evaluated in the terrestrial and/or aquatic food chain model. As shown in Table 9-40, the refined scenario NOAEL HQ for zinc was greater than 1 for the short-tailed shrew, and the refined scenario NOAEL HQs for lead and zinc were greater than 1 for the American robin. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of lead and zinc in surface soil, while the potential does exist for unacceptable risk to individual insectivorous mammals and birds exposed to surface soils containing affected concentrations of lead and zinc, population-level effects are considered unlikely.

As shown in Table 9-41, the refined scenario NOAEL HQ for the mink and great blue heron were all below 1, indicating no risk to piscivorous species. Therefore, effects are not expected for aquatic life exposed to bioaccumulative COPECs in sediment and/or surface water at the WBG.

9.9 WBG Summary and Conclusions

The WBG was formerly used as a burning ground to decontaminate explosives contaminated material and to dispose of excess and off-spec explosives/energetics during historical site operations. The main burn area was approximately 170 ft long by 100 ft wide and is surrounded on three sides by an approximately 4 ft high earthen berm. A dirt road runs parallel to the open side of the former burn area, leading north to Alger Road, and south to the top of a steep slope above an unnamed pond. The dirt road was reportedly constructed on top of an ashy layer of material extending from the burning ground at the time of the pond construction. The pond was constructed during the early 1990s and is fed by Wiggins Spring at the northwest (upgradient) end of the pond. The pond also collects runoff from the surrounding area through a series of storm water ditches/culverts. The WBG is no longer active.

Site characterization activities performed at the WBG from 1997 through 1999 indicated the presence of an ashy layer of material throughout the burn area and elevated concentrations of inorganics and PAHs in burn area soils. A test pitting program completed in 1999 effectively removed all of the soils containing elevated constituent concentrations from the former burn area; therefore, the burn area no longer poses an environmental concern. Samples collected in 1999 from the berms surrounding the former burn area had no constituents above applicable screening levels or background inorganics concentrations; therefore, the berms do not appear to have been affected by operations at the site.

Investigations performed at the WBG between 1998 and 2008 have focused on characterizing and delineating constituent detections outside of the former burn area. Areas that have been investigated have included the access road on the northwest side of the burn area; surface and subsurface soils located downgradient from the burn area; sediments and surface water in the unnamed pond; sediments and surface water in the unnamed creek downgradient of the pond; and a former transformer location.

Analyte classes included in the WBG investigation have included VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides, dioxins/furans, explosives, and inorganics.

One of the primary areas of investigation at the WBG has been the dirt access road which runs along the open side (northwestern side) of the former burn area. During the course of investigation at the site, an ashy layer of material was identified in the subsurface (approximately 2-4 ft bgs) under the road that was very similar to the ashy soils that had been present in the burn area. It is believed that this ashy layer of material was likely pushed out of the former burn area during regrading activities that would have been performed between burning events. This ashy layer was likely buried when the dirt road was constructed to the pond. The extent of the ashy layer was delineated by extensive soil boring activities completed in 1994 and 2004 and is confined to the subsurface soils underneath the road.

With the exception of one subsurface soil sample at the end of the access road [WBGSB22(2-4 ft bgs)] no constituents were detected above applicable screening levels in any of the surface or subsurface soil samples in this area (including within the ashy layer of material). The sample collected from 2 to 4 ft bgs at soil boring WBGSB22 contained inorganics (arsenic, chromium, iron, lead), one PCB (Aroclor 1254), PAHs [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene], and one dioxin (1,2,3,7,8 PeCDD) at concentrations above applicable screening levels. Samples collected from 0 to 0.5 ft bgs and 6 to 8 ft bgs at soil boring did not contain any constituents above applicable screening levels; nor did any other soil boring collected around WBGSB22. Therefore, the detections appear to be isolated to a very small area. Aluminum was also detected in one other subsurface soil sample in the road area [WBGSB23(6-8 ft bgs)] at a concentration slightly above background and the residential screening level.

Surface and subsurface soil samples were also collected downgradient (northwest, west, and south) of the burning ground and road to evaluate the potential for constituents to have migrated outside the burn area. The results from these areas indicated:

- Despite the fact that the former burning ground operations were used to decontaminate and dispose of materials that had been in contact in explosive/energetic compounds, explosives were not found to be a concern at the site. Only one explosive compound was ever detected during the course of sampling at a single location. Penterythritol tetranitrate was detected at a concentration of 0.11 mg/kg at surface soil at WBGSB24.

- Seventeen different PAHs were detected in surface and subsurface soil outside of the former burn area. Benzo(a)pyrene was detected at a concentration above the industrial RSL in two surface soil samples (WBGSB24 and WBGSB25). Benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene were also detected in these samples at concentrations above residential RSLs. The WBGSB24 and WBGSB25 sample locations are in a small drainage pathway located west, and downslope, from the former burn area. This area receives runoff from the former burn area and from the surrounding RFAAP-NRU roads and flows into the pond.

- No PCBs were detected in the soil sample collected at the former transformer location.

The pond sediment sampling activities indicated that lead and chromium were present at concentrations above background levels and surface soil RSLs in samples collected in an isolated 2,100 ft^2 area near the northern bank of the pond. The outer perimeter of the area containing the lead and chromium concentrations above applicable screening levels has been delineated through the collection of multiple samples for both laboratory analysis and XRF field screening. The PAHs benzo(a)pyrene, benzo(a)anthracene and benzo(b)fluoranthene were detected at concentrations above residential RSLs in three samples located in the northwestern portion of the pond (SD-01, WBGSD12, and WGSD16). These samples were located near points where surface water drainage ditches enter the pond. The explosive nitroglycerine was detected in one pond sediment sample at a concentration above the residential RSL. Several dioxins/furans were also detected in pond sediment samples; however the all detected constituents were below residential RSLs.

A total of six sediment samples were collected from the stream downgradient of the outfall of the unnamed pond. Arsenic and iron were detected in one sample (WBGSD13) in 2002 at concentrations above background and applicable screening levels. The PAHs benzo(a)pyrene, benzo(a)anthracene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene were also detected at concentration above applicable screening levels in one sediment sample collected in 2002 (WBGSD09). A second sample collected at this location in 2008 (WBG-SE006) indicated that only benzo(a)pyrene was present at a concentration above a residential screening level. No other constituents were detected at concentrations above applicable RSLs.

Surface water samples collected from the pond and the unnamed stream indicated the following:

- Lead was detected at concentrations above the USEPA tap water RSL and ecological screening levels in four surface water samples from the pond. These samples were all collected in the area where the elevated concentrations of lead were detected in sediment. Lead was not detected above applicable screening levels in any samples from the stream.

- Arsenic was detected above the tap water RSL in two samples collected from the pond in 1999. Arsenic was not detected in any other samples collected from the pond or from the stream throughout the remainder of the investigation.

- Iron, manganese, and thallium were detected above the tap water RSL values in single samples collected from the stream near the pond outfall. The herbicide MCPP was also detected in one sample from the stream at a concentration above the tap water RSL.

- The pesticide dieldrin was detected in two samples (WBGSW08 and WBGSW14) at concentrations above tap water RSLs. Sample location WBGSW14 was in the unnamed stream that flows through the RFAAP-NRU, upstream of the confluence with the stream from the WBG. This indicates the possible presence of a dieldrin source somewhere off of the facility.

- Perchlorate and tetrachloroethene were also detected in the WBGSW14 sample at concentrations above tap water RSLs. These constituents were not detected in any other surface water, sediment, or soil samples at the WBG.

- The VOC chloroform was detected in two pond water samples and two stream samples during the 2002 investigation at concentrations above the tap water RSL.

The HHRA evaluated potential current exposure of site workers to surface soil, surface water, and sediment, potential future exposures of construction workers to total soil and potential future adult and child resident exposure to total soil, surface water, sediment, and fish caught in the pond at the WBG. The soil, sediment, and surface water COPCs were evaluated for direct contact. In addition, the HHRA evaluated potential exposures to participants in the semi-annual fish rodeo and exposures to hypothetical workers and hypothetical residents under future conditions if the pond were drained.

Potential risks and hazards for site workers and construction workers, including exposure to lead, under current industrial land use conditions were within generally acceptable levels or below benchmarks. Similarly, exposures to participants in the fish rodeo were within acceptable levels and below benchmarks. Under a hypothetical future residential land use, including merged soil and sediment to represent conditions were the pond to be drained, potential hazards associated with chromium in sediment were slightly greater than 1 for the child resident. Potential risks associated with residential exposure to lead in soil and sediment could also result in adverse health effects. The predication of elevated blood lead levels was driven by the concentration of lead in the pond sediment, primarily at one location. No other scenarios evaluated resulted in an unacceptable risk levels.

A SLERA and BERA were completed for the WBG, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial food chain model indicate that while some of the NOAEL and LOAEL HQs were greater than 1, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, adverse effects of these COPECs at the population-level are unlikely at the WBG.

Similarly, the results of the sediment and surface water evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the aquatic food chain model indicate adverse effects are not expected for aquatic life exposed to bioaccumulative COPECs in sediment and/or surface water at the WBG.

The environmental investigations completed at the WBG have successfully delineated the nature and extent of elevated constituent concentrations in soils, sediments, and surface water. The results of the investigation and the corresponding human health and ecological risk assessments indicated that the potential risks associated with the site are within acceptable ranges for industrial use of the site. Under a potential future residential use scenario, the potential hazard was above the acceptable range due to the presence of chromium and lead in a small area of pond sediments. Based on the potential residential risks associated with the lead and chromium in the pond sediments, it is recommended that a FS be conducted to evaluate potential remedial options for the pond sediments. This remedial alternative analysis will include a no-action alternative which may be viable for the site based on the very limited distribution of lead and chromium in the pond sediments.

10. RFAAP-NRU Groundwater

Groundwater at the RFAAP-NRU is considered on a facility-wide basis, rather than specific to any of the individual Study Areas. The groundwater site conceptual model that has been developed for the facility is presented in Section 3. A summary of the investigation activities that have been performed to assess groundwater quality is presented within this section. As with the individual Study Areas discussed in the previous sections, human health and ecological risk assessments are also presented for groundwater.

10.1 Environmental Setting and Conceptual Site Model

The geologic and hydrogeologic setting of the RFAAP-NRU are presented in Section 3 of this report along with the groundwater site conceptual model.

10.2 Environmental Investigations

The groundwater investigation activities at the RFAAP-NRU commenced in 2007 and have included:

- 2007 – Groundwater Investigation by Shaw;
- 2008 – Remedial Investigation by ARCADIS; and
- 2010 – Remedial Investigation by ARCADIS.

The goals and findings of these investigations are summarized in the following sections. As discussed in Section 4.1, the constituent detections reported in the investigation summaries are compared to the tap water RSLs.

10.2.1 June 2007 Groundwater Investigation

Shaw's 2007 groundwater investigation activities included the installation of 11 groundwater monitoring wells at the RFAAP-NRU. The wells were all installed at the Study Areas in western portion of the facility. The well installation activities at each of the Study Areas are presented below.

- Bag Loading Area - Two monitoring wells were installed at the BLA to provide an assessment of groundwater quality at and downgradient of the site. One of the wells (BLAMW01) was installed near the center of the site, within the "L" formed by Building 405. The second well (BLAMW02) was installed

RFAAP-NRU Facility-Wide Groundwater

downgradient from Building 405, on the hillside sloping down to the unnamed creek. Bedrock was encountered at a shallow depth in both borings (i.e. approximately 2 ft bgs at BLAMW02 and 31 ft bgs at BLAMW01). Both wells were installed in the bedrock at the first encountered water, at depths of 221 ft bgs (BLAMW-01) and 151 ft bgs (BLAMW-02). A site map of the BLA depicting the monitoring well locations is presented in Figure 6-2

- Igniter Assembly Area – Four groundwater monitoring wells were installed at the IAA in areas suspected to be down gradient from the site. One of these wells (IAAMW-01) was installed near the buildings in the central portion of the site that are known to contain conductive flooring. This well was installed at the bedrock-overburden interface (34 ft bgs). One well (IAAMW02) was installed downgradient from the site to the southwest, near a photolineament trending to the southwest. This well was installed in the bedrock at a total depth of 160 ft bgs. A third well (IAAMW03) was installed near the southeast corner of the IAA at a depth of 77 ft bgs. The fourth well (IAAMW04) was installed near the Rail Yard and the unnamed creek that drains the western portion of the RFAAP-NRU. This well was installed to a depth of 88 ft bgs. Site maps of the IAA and the RY that depict the monitoring well locations are presented in Figure 7-2 and 8-2.

- Northern Burning Ground – Two wells (NBGMW01 and NBGMW02) were installed at the NBG to assess whether groundwater quality had been affected by the historical burning ground activities conducted at this site. As discussed in the EE/CA prepared for the NBG (ARCADIS 2009b) lead and chromium were identified as COCs in surface soil at the NBG. Monitoring well NBGMW01 is located in the central portion of the NBG, where the highest concentrations of lead and chromium were detected in surface soil. Monitoring well NBGMW02 was installed to the north of NBGMW01, near the RFAAP-NRU boundary fence. A site map of the NBG depicting the monitoring well locations is presented in Figure 10-1.

- Western Burning Ground – Three wells were installed at the WBG to assess whether groundwater quality had been affected by the historical burning ground activities conducted at this site. One monitoring well (WBGMW01) was installed near the center of the former burning area, where 1998 test pitting/soil excavation activities were completed. The other two monitoring wells (WBGMW02 and WBGMW03) at this site were located between the former burning ground and the unnamed pond located to the south. A site map of the

WBG depicting the monitoring well locations is presented in Figures 9-2 and 9-3.

The well installation activities completed at the RFAAP-NRU are discussed in further detail in Shaw's 2007 report entitled NRU Additional Characterization Sampling and Groundwater Investigation Data Report (Shaw 2007). A summary of the well construction details is presented in Table 3-1. A site map of the RFAAP-NRU facility that depicts the locations of the monitoring wells is presented in Figure 3-2.

Shaw completed the first groundwater sampling event at the RFAAP-NRU between June 18 and June 21, 2007. The groundwater monitoring event included all eleven monitoring wells at the facility. The wells were sampled for VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides, explosives, dioxins/furans, inorganics, total organic carbon, and total organic halides. The laboratory analytical results for the 2007 groundwater samples are summarized in Table 10-1.

VOCs. Three VOCs (acetone, toluene, and chloroform) were detected in isolated groundwater samples (see Table 10-1). Acetone was detected in two monitoring wells (BLAMW02 and WBGMW01) and toluene was detected in one monitoring well (BLAMW01). The laboratory validation process indicated that both of these constituents were also detected in an associated laboratory blank sample, therefore, the reported detections are not believed to be site related. It should also be noted that the detected concentrations of acetone and toluene, were several orders of magnitude below tap water RSLs. Chloroform was detected in one sample (WBGMW01) at a concentration above the tap water RSL of 0.19 µg/L but below the MCL of 70 µg/L. Chloroform is a common laboratory contaminant and this detection is not believed to be site related. Chloroform was not a COPC for soil at the WBG.

SVOCs. There were no detections of SVOC's in any of the groundwater samples.

PAH's. There were no detections of PAH's in any of the groundwater samples.

PCBs. There were no detections of PCB's in any of the groundwater samples.

Pesticides. There were no pesticides detected in any of the groundwater samples.

Herbicides. There were no herbicides detected in any of the groundwater samples.

RFAAP-NRU Facility-Wide Groundwater

Explosives. Perchlorate was detected in several samples (IAAMW01, IAAMW02, IAAMW04, NBGMW01, NBGMW02, WBGMW02, and WBGMW03). All of the reported concentrations were several orders of magnitude below the tap water RSL of 26 µg/L (see Table 10-1). Laboratory data validation also indicated that perchlorate was detected in a laboratory blank associated with these samples; therefore, the detections are not believed to be site related. No other explosives were detected in any of the samples.

Dioxins/Furans. Several dioxin/furan compounds were detected in the groundwater samples (see Table 10-1). However, the majority of the detected constituents were present at concentrations that were quantified as estimated by the laboratory (i.e., J-flagged) or were also detected in a laboratory blank sample associated with the analyses. The reported concentrations of 1,2,3,7,8-PeCDF, 2,3,4,7,8-PeCDF, 2,3,7,8-TCDD, 2,3,7,8-TCDF were above the tap water RSLs in several of the groundwater samples.

Inorganics. Several inorganics were detected in the groundwater samples from all of the RFAAP-NRU monitoring wells (see Table 10-1). The analytical results indicated that the concentrations of arsenic at IAAMW01 (20.9 µg/L) NBGMW01 (6.3 µg/L), and WBGMW01 (8.20 µg/L), were above the tap water RSL. Iron (83,300 µg/L) and manganese (1,790 µg/L) were also detected at concentrations above the tap water RSL at IAAMW01. None of the other detected inorganics were present at concentrations above tap water RSLs.

Total Organic Carbon. Total organic carbon was found to range from less than 1,000 µg/L to 80,700 µg/L at BLAMW02 (see Table 10-1).

Total Organic Halides. The total organic halides analysis indicated resulted in no detections.

10.2.2 October 2008 Groundwater Investigation

In accordance with Remedial Investigation Work Plan Addendum 27 (ARCADIS 2008b), ARCADIS completed a second groundwater sampling event at the RFAAP-NRU on September 24, 25, and October 3, 2008. This event included collecting groundwater samples from all eleven monitoring wells at the facility. Samples were also collected from four springs that have been identified at the RFAAP-NRU. One spring water sample (WBG_Spring001) was collected from Wiggin's Spring at the WBG. A second spring water sample (RY_Spring002) was collected at the unnamed spring at the RY pond. Two spring water samples (NSpring003 and NSpring004) were also collected at unnamed springs located in the northeast corner of the RFAAP-NRU. The groundwater monitoring wells were all sampled for total TAL inorganics. Where low flow sampling techniques were unable to reduce turbidity to below 40 NTUs samples were also collected for dissolved TAL inorganics analysis. The spring water samples were analyzed for TAL inorganics and PAHs. The results of the field parameter analyses and the laboratory analytical results for the groundwater and spring water samples are summarized in Table 10-2 and the sample locations are depicted in Figure 3-2. The laboratory analytical reports for the 2008 groundwater sampling event are in Appendix G.

The analytical results from the spring water samples indicated that several inorganics were present, but that the detected concentrations were all below tap water RSLs. The PAH naphthalene was detected in the spring water samples from RY_Spring002 (0.044 µg/L) and WBG_Spring_001 (0.032 µg/L). Phenanthrene was also detected in the RY_Spring002 sample at a concentration of 0.038 µg/L. The detected concentrations of naphthalene and phenanthrene were below tap water RSLs.

The low flow sampling techniques utilized during the groundwater sampling activities were unsuccessful at lowering the turbidity below 40 NTUs at monitoring wells BLAMW02, IAAMW01, IAAMW03, IAAMW04, NBGMW01, and NBGMW02. Therefore, these wells were sampled for both total and dissolved (filtered) TAL inorganics. The laboratory analytical results indicated that the two wells with the highest turbidity readings (IAAMW01 and NBGMW02) had the highest detected concentrations of total inorganics, and the only inorganics detected at concentrations above tap water RSLs. The concentrations of arsenic (24.1 µg/L) and iron (51,000 µg/L) were above tap water RSLs at IAAMW01. The detected concentrations of aluminum (38,700 µg/L), arsenic (20.6 µg/L) and iron (44,400 µg/L) at NBGMW02 were also above tap water RSLs. These inorganics were not detected in the dissolved inorganics analysis at IAAMW01 and NBGMW02. In general the far fewer inorganics were detected in the dissolved inorganics analysis in comparison to the total inorganics analysis. Total inorganics concentrations were also much lower in the monitoring wells with lower turbidity readings.

In conformance with the Remedial Investigation Work Plan Addendum 27 (ARCADIS 2008b), ARCADIS attempted to install a groundwater monitoring well at the BDDT to evaluate the potential transport of PAH compounds to groundwater from the surface soils. Two borings were completed at the BDDT, one to 50 ft bgs and a second to 75 ft bgs. Bedrock was encountered at approximately 5 ft bgs in both borings. Groundwater was not encountered in either boring; therefore no wells were installed at the BDDT.

10.2.3 April 2010 Groundwater Investigation

ARCADIS completed a third groundwater sampling event at RFAAP-NRU during 2010 to supplement the existing data set at the request of VDEQ. This sampling event was conducted on April 6-7, 2010 and included collection of groundwater samples from all eleven monitoring wells at the facility. In addition, the four springs that were sampled during the October 2008 sampling event were also sampled during the 2010 event.

As in the 2008 sample event, one spring water sample (WBG_Spring001) was collected from Wiggin's Spring at the WBG. A second spring water sample (RY_Spring002) was collected at the unnamed spring at the RY pond. Two spring water samples (NSpring003 and NSpring004) were also collected at unnamed springs located in the northeast corner of the RFAAP-NRU.

The groundwater monitoring wells were all sampled for the following analytes: VOCs, PAHs, PCBs, explosives, total TAL inorganics, and dissolved TAL inorganics. Where low flow sampling techniques were unable to reduce turbidity to below 40 NTUs, the dissolved TAL inorganics data was used preferentially over the total inorganics data for the risk assessment. The five monitoring wells located at the two former burning ground sites (NBG and WBG) were also analyzed for dioxins/furans. The spring water samples were analyzed for the following: VOCs, PAHs, PCBs, explosives, and total TAL inorganics.

The results of the field parameter analyses and the laboratory analytical results for the groundwater and spring water samples are summarized in Table 10-3 and the sample locations are depicted in Figure 3-2. The laboratory analytical reports for the 2010 groundwater sampling event are in Appendix G.

VOCs. Five VOCs (acetone, carbon disulfide, chloroform, chloromethane, and MTBE) were detected in groundwater samples (see Table 10-3). Acetone was detected in 4 of the 15 following sample locations: IAA-MW002, IAA-MW004, BLA-MW002, and WBG-MW002. The highest acetone concentration occurred at WBG-MW002 with a reported value of 41.4 µg/L. Chloromethane was detected in a majority of the samples (i.e., 13 of the 15 sample locations) with a minimum concentration of 0.93 µg/L at sample location IAA-MW004 and a maximum concentration of 1.7 µg/L at sample location WBG-MW001. Detects of both carbon disulfide and MTBE were isolated to sample location IAA-MW002 with a concentration of 0.448 µg/L and 11.4 µg/L, respectively. Chloroform was also detected in a single sample (WBG Spring001) at a concentration of 0.85 µg/L, which is higher than the tap water screening value of 0.19 µg/L. It should be noted that other than the single chloroform detection, all of the detected concentrations of VOCs within the groundwater were below the tap water RSLs.

PAH's. There were only three sample locations (two monitoring wells and one spring sample) that had detections for PAHs (Table 10-3). Of the monitoring wells, BLA-MW001 had detects of phenanthrene (0.0223 µg/L) and pyrene (0.0194 µg/L). Monitoring well IAA-MW002 had a detection for fluoranthere with a concentration of 0.0189 µg/L. Finally, spring location RY-SPRING002 had a detection for anthracene with a reported concentration of 0.0213 µg/L. All of these PAH detections are several orders of magnitude below the tap water RSLs.

PCBs. There were no detections of PCB's in any of the groundwater samples (Table 10-3).

Explosives. The following five explosive constituents were detected: nitrobenzene, PETN, tetryl, p-nitrotoluene, and 2,6-dinitrotoluene (Table 10-3). Nitrobenzene was detected in monitoring well NBG-MW003 at a concentration of 0.512 µg/L, which is greater than the tap water RSL of 0.012 µg/L. PETN was detected in monitoring well IAA-MW002 with a concentration of 1.39 µg/L. Tetryl was detected in both the monitoring well NBG-MW002 and within the spring samples RY-SPRING002 with a respective concentration of 0.450 µg/L and 0.302 µg/L. 2-Nitrotoluene was detected in monitoring well BLA-MW002 with a concentration of 0.293 µg/L. Finally, 2,6-dinitrotoluene was detected in NBG-MW002 with a concentration of 0.393 µg/L. With the exception of the single nitrobenzene detection, the explosive detections were lower than their respective tap water RSLs.

Dioxins/Furans. The only dioxin compound detected was OCDD within sample WBG-MW001. The OCDD concentration at this location was 0.249 ng/L, which is below the tap water RSL of 1.7 ng/L (Table 10-3).

Inorganics. The groundwater monitoring wells were analyzed for both total metals and dissolved metals. Six of the eleven monitoring wells had total metals detections of one or more of the following six constituents at concentrations at or above the tapwater RSL: arsenic, aluminum, cobalt, iron, lead, and manganese. Arsenic was detected at a concentration above the tap water RSL of 0.045 µg/L at Monitoring Wells IAA-MW001, IAA-MW002, IAA-MW004, WBG-MW001, WBG-MW002, and WBG-MW003.

Aluminum was detected above the RSL of 37,000 µg/L at Monitoring Well IAA-MW004. Cobalt and lead were detected above their respective RSL of 11 µg/L and 15 µg/L at IAA-MW004 and WBG-MW001. Iron and manganese were both detected above their respective RSLs of 26,000 µg/L and 3,500 µg/L at Monitoring Well IAA-MW004. No inorganics were detected at concentrations above tap water RSL in Monitoring Wells BLA-MW001, BLA-MW002, IAA-MW003, NBG-MW001, and NBG-MW002 or in any of the spring water samples.

As demonstrated during the 2008 sampling event, the presence of suspended solids (i.e., high turbidity values) in the groundwater samples is known to result in higher concentrations of the detected metals in the total inorganics analyses. This was again confirmed during the 2010 sampling event as the concentrations of the detected metals were much lower in the samples analyzed for dissolved inorganics analyses versus the total inorganics analyses. The only constituent detected above tap water RSLs in the dissolved inorganics samples was arsenic, which was detected at a single monitoring well location (IAA-MW002) at a concentration of 1.83 µg/L.

10.3 Nature and Extent of Constituent Detections

A total of three groundwater sampling events have been completed at the RFAAP-NRU and have included a total of eleven monitoring wells installed at the BLA, IAA, NBG, and WBG sites. The monitoring activities have also included the collection of spring water samples from four springs located throughout the facility. The analytical results from the monitoring activities have indicated that metals are present in groundwater at RFAAP-NRU (see analytical results for groundwater and spring samples in Tables 10-1, 10-2, and 10-3). All of the detected metals are naturally occurring in soil at the facility (see background inorganics concentrations in Table 4-2) and the detected concentrations were generally below tap water RSLs. During the course of monitoring arsenic, aluminum, cobalt, iron, lead, and manganese have been detected at concentrations above their respective RSLs in isolated monitoring wells. These detections have been demonstrated to be the result of suspended solids (i.e., elevated turbidity levels) in the groundwater samples. The metals concentrations detected in the monitoring wells decreased when the samples were collected using low-flow sampling techniques. The concentrations of metals detected in dissolved (i.e., filtered) groundwater samples were also far lower than corresponding samples analyzed for total metals. The only inorganic constituent detected above applicable tap water RSLs in samples analyzed for dissolved metals was arsenic. Arsenic was detected in a single groundwater sample (IAA-MW002) during the 2010 sampling event at a concentration above the tap water RSL of 0.045 µg/L.

RFAAP-NRU Facility-Wide Groundwater

During the 2007 groundwater sampling event, several dioxin/furan compounds were reportedly detected in the samples from many of the monitoring wells. However, the majority of the detected constituents were present at concentrations that were qualified as estimated by the laboratory (i.e., J-flagged) or were also detected in a laboratory blank sample associated with the analyses. The reported concentrations of 1,2,3,7,8-PeCDF, 2,3,4,7,8-PeCDF, 2,3,7,8-TCDD, 2,3,7,8-TCDF were above the tap water RSLs at several of the groundwater monitoring wells. When the monitoring wells and spring locations were sampled during the 2010 groundwater sampling event the only dioxin compound detected was OCDD. OCDD was detected in a single monitoring well (WBW-MW001) at a concentration that was an order of magnitude less than the tapwater RSL. There were no issues with laboratory blank contamination during the 2010 sampling event, indicating that the results from the 2010 sampling event are more indicative of actual groundwater quality at the site.

A few explosive compounds (PETN, tetryl, p-nitrotoluene, 2,6-dinitrotoluene, and nitrobenzene) were detected at low concentrations in isolated groundwater samples during the 2010 sampling event. The detected concentrations of these constituents were several orders of magnitude below their respective RSLs, with the exception of nitrobenzene. Nitrobenzene was detected in one monitoring well (WBG-MW003) at a concentration of 0.512 µg/L, which is slightly higher than the tap water RSL of 0.12 µg/L. No explosives were detected in groundwater during the 2007 sampling event.

Samples collected from the four springs during the 2008 and 2010 groundwater sampling event did not contain any constituents at levels above applicable RSLs, with the exception of one chloroform detection at WBG-Spring001 during the 2010 sampling event. It should be noted that the chloroform detection at WBG-Spring001 was J-flagged by the laboratory. The results of the spring samples indicate there are no large scale water quality issues at the RFAAP-NRU.

10.4 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. The groundwater risk assessment dataset was prepared then summarized and statistically analyzed per methods described in Appendix A. The groundwater risk assessment dataset summary highlighting: the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPC is presented in Table 10-3.

While the spring samples were evaluated for both human health and ecological risk, the remaining groundwater samples were only evaluated for human health risk, as exposure to groundwater by ecological receptors is unlikely. Among the three sampling events (2007, 2008, and 2010), adequate data were available to exclusively use data from filtered samples for assessing risk through exposure to dissolved phase inorganic constituents in groundwater used as a potable water supply. The ecological risks for the spring samples collected at the RY and the WBG were evaluated as part of the surface water data sets collected at those sites, and are discussed in Sections 6 and 7, respectively. Due to the Karst formation and the localized presence of iron in some groundwater samples, the presence of colloidal particles measured as turbidity in the groundwater samples resulted in elevated levels of trace metals. Therefore, when the turbidity could not be reduced below 10 NTUs by low flow sampling techniques, following USEPA (USEPA 2002e) guidance both filtered and unfiltered groundwater samples were collected. For the purposes of assessing risk through exposure to dissolved phase constituents in groundwater used as a potable water supply, if the turbidity was elevated, metals data from the filtered samples were quantitatively evaluated; however, if the turbidity was less than 10 NTUs, the metals data from the unfiltered sample was quantitatively evaluated.

10.5 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with potential exposure to constituents detected in groundwater samples collected at the RFAAP-NRU. This section summarizes the occurrence of constituents in groundwater, identifies groundwater COPCs, and presents the estimated human health risks associated with the relevant human exposure scenarios. The methodologies for the selection of COPCs, the exposure assessment, and the toxicity assessment for the HHRA are presented in Appendix A. The results are summarized below.

10.5.1 Selection of Constituents of Potential Concern

Groundwater COPCs were selected by comparing the analytical data with USEPA (2009a) adjusted tap-water RSLs. Table 10-4 presents the selection of groundwater COPCs for the HHRA. As summarized in Table 10-5, chloroform and dioxin/furan compounds were the main organic constituents that were identified as groundwater COPCs. Two explosive compounds were also detected and selected as COPCs. The inorganic constituents identified as groundwater COPCs were: arsenic, iron, and manganese. Exposure point concentrations for COPCs are presented in Table 10-5.

10.5.2 Human Health Risk Characterization

Although groundwater is not currently used at the NRU, a site worker exposure to groundwater used as a potable water supply was evaluated along with exposure to volatile COPCs migrating to indoor air. In addition, a future hypothetical residential exposure to groundwater used as a potable water supply was evaluated. Potential future residential groundwater exposure pathways include direct contact pathways if groundwater were used as a potable water supply and inhalation of volatile COPCs in groundwater. The inhalation pathway is potentially complete under two scenarios. Volatile COPCs can be present in ambient air from water used as a potable water supply (e.g., during showering). Volatile COPCs can also migrate to indoor air through subsurface vapor intrusion.

The excess lifetime cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the RFAAP-NRU are presented in Appendix A and are summarized in the table and subsections below.

10.5.2.1 Hypothetical Future Residents

Residential development of the NRU is not expected to occur and the current land use associated with the site is not expected to change. As a result, future use of the site for residential purposes is considered unlikely, but was considered as a conservative measure. Risk to the potential future resident receptor from exposure to groundwater was evaluated. Risks were estimated for all COPCs. For inorganic COPCs, risks were calculated using EPCs based on both the filtered and unfiltered groundwater samples.

The ELCR and non-cancer hazard index for hypothetical future adult or child resident exposure to groundwater are presented in Appendix A, and are summarized in Table 10-6.

The total cumulative ELCR for hypothetical future residents exposed to groundwater is 2×10^{-4}, which is above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future adult residents is 0.6, which is below the benchmark of 1. The total cumulative HI for hypothetical future child residents is 1, which is equal to the benchmark of 1. The risk drivers for cancer risk were arsenic and the combined dioxin and furan congeners. During the 2010 sampling event, arsenic was only detected in one filtered sample (IAA-MW02) at a concentration (1.83 µg/L) that was below the Federal maximum contaminant level (MCL) of 10 µg/L. Arsenic was not detected in any of the filtered samples during the 2008 sampling event. The dioxin and furan congeners that are driving the cancer risks were detected in several groundwater samples during the 2007 sampling event at concentrations greater than the USEPA RSLs. However, most of these constituents were also detected in the rinse blank associated with those samples, which indicated a potential cross contamination issue with the sampling or laboratory equipment. All of the detections during the 2007 sampling event were also below the reporting limit and were qualified as "estimated". During the 2010 sampling event, only one dioxin constituent was detected in a single monitoring well, and the concentration was well below the USEPA RSL, which further indicates dioxin/furan detections from the 2007 sampling event are likely not indicative of groundwater quality at RFAAP-NRU.

10.5.2.2 Site Worker

A current or future site worker could be present at the NRU, and could be exposed to groundwater as a potable source or via inhalation of vapors due to subsurface vapor intrusion into a building. Risks to commercial/industrial receptor exposed to vapors indoors due to subsurface vapor intrusion were assessed using the USEPA vapor intrusion model. The ELCR and non-cancer hazard index for site worker exposure to groundwater are presented in Appendix A. For inorganic COPCs, risks were calculated using EPCs based on combined filtered and unfiltered groundwater samples.

The ELCR for site workers potentially exposed to potable groundwater is 4×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The HI for site workers is 0.4, which is below the benchmark of 1.

The ELCR for a site worker exposure to vapors in indoor air due to subsurface vapor intrusion was 2×10^{-8} and is well below the generally accepted USEPA target risk range of 1×10^{-6} to 1×10^{-4}.

As previously stated, including unfiltered data for calculating EPCs for inorganic COPCs is highly conservative and not reflective of conditions most likely to occur in the unlikely event that groundwater is used as a potable water supply in the future.

10.6 RFAAP-NRU Groundwater Summary and Conclusions

The groundwater investigation activities at the RFAAP-NRU have included the installation of 11 groundwater monitoring wells and groundwater sampling events in 2007, 2008, and 2010. In addition to sampling all of the monitoring wells, the 2008 and

RFAAP-NRU Facility-Wide Groundwater

2010 events also included the collection of samples from 4 springs located within the boundaries of the RFAAP-NRU. The spring samples were collected because the function of springs as groundwater collectors makes them ideal locations for screening for groundwater quality.

The 2007 groundwater sampling event included the collection of groundwater samples from 11 monitoring wells located throughout the RFAAP-NRU. The wells were installed at, or in the vicinity of, the Study Areas at the RFAAP-NRU due to the known historical operations conducted at them. Four wells (IAA-MW01 through IAA-MW04) are located in the vicinity of the IAA, three wells (WBG-MW01 through WBG-MW03) are located at the WBG, two wells (BLA-MW01 and BLA-MW02) are located at the BLA, and two wells (NBG-MW01 and NBG-MW02) are located at the NBG. The monitoring wells were analyzed for a full suite of parameters including dioxins/furans, explosives, herbicides, pesticides, PAHs, PCBs, SVOCs, VOCs, and inorganics. The results indicated the following:

- No SVOCs, PAHs, PCBs, pesticides, or herbicides were detected in any of the groundwater samples.

- The VOC chloroform was detected in one sample (WBGMW01) at a concentration above the tap water RSL. Chloroform was not detected at any other sample locations

- Several dioxin/furan related compounds were reported at low concentrations in all of the groundwater samples. Despite the low concentration, some of these constituents were above the tap water RSLs. However, the detected constituents were qualified due to the detection of dioxins and furans in laboratory blank samples. Dioxins and furans were not identified as primary COCs in soil at any of the Study Areas, therefore, it is unlikely that the reported detections in groundwater are associated with RFAAP-NRU.

- Several inorganic constituents were detected in all of the groundwater samples collected during the 2007 investigation. In most cases the detected concentrations were below applicable tap water RSLs; however three samples contained constituents at concentrations above the tap water RSLs. The sample from Monitoring Well IAA-MW01 had arsenic, iron, lead, and manganese at concentrations above applicable RSLs. Monitoring Well NBG-MW01 had arsenic at a concentration above the tap water RSL (note that arsenic was also detected in a laboratory blank sample associated with this sample). Monitoring Well WBG-MW01 had arsenic and lead at concentrations above the RSLs (again note that arsenic was detected in a laboratory blank sample associated with this sample).

ARCADIS conducted a groundwater sampling event at the RFAAP-NRU in 2008 to evaluate whether suspended solids and naturally occurring inorganics in soils could have contributed to the elevated inorganics concentrations observed during the 2007 groundwater sampling event. ARCADIS utilized low flow sampling techniques to sample all eleven groundwater monitoring wells at the facility to reduce the presence of suspended solids in the groundwater samples. When the low flow sampling techniques were unable to lower turbidity readings below a threshold of 40 NTUs, samples were collected for both total and filtered laboratory analysis. The results of this sampling event indicated the following:

- There was a strong correlation between the presence of suspended solids and elevated inorganics concentrations. Inorganics concentrations were typically lower in samples with lower turbidity readings. Samples that were analyzed after filtering also illustrated a large drop in inorganics concentrations.

- The unfiltered samples collected at monitoring wells IAA-MW01 and NBG-MW02 had concentrations of aluminum, arsenic, iron, lead and manganese at concentrations above applicable tap water RSLs. These samples, which were the only wells sampled with inorganics concentrations above applicable RSLs, both had turbidity readings above 1,000 NTU. The analytical results from the filtered samples at these locations indicated a significant drop in inorganics concentrations and no constituents were detected at concentrations above applicable RSLs.

The 2008 groundwater sampling event also included the collection of four spring water samples. One sample (WBG-Spring001) was collected from Wiggin's Spring at the head of the WBG pond, one sample (RY-Spring002) was collected from the unnamed spring at the head of the RY pond; the other two spring samples (NSpring003, and NSpring004) were collected from unnamed springs located in the northeastern portion of the RFAAP-NRU. The samples were analyzed for inorganics and PAHs. The samples had very low turbidity and indicated that several inorganics were present at concentrations below applicable tap water RSLs. The presence of these metals in groundwater should be expected due to naturally occurring inorganics in soil at the RFAAP-NRU. The PAH naphthalene was detected in the samples from the WBG and RY springs. Phenanthrene was also detected at the RY spring. The concentrations of naphthalene and phenanthrene were several orders of magnitude below applicable tap water RSLs.

ARCADIS completed a third round of groundwater sampling at RFAAP-NRU during 2010 at the request of the VDEQ. This event included collecting groundwater samples from all eleven monitoring wells at the facility in addition to the four springs that were sampled during the October 2008 sampling event. The groundwater monitoring wells were all sampled for the following analytes: VOCs, PAHs, PCBs, explosives, dissolved metals, total TAL inorganics, and dissolved TAL inorganics. The five monitoring wells located at the two former burning ground sites (NBG and WBG) were also analyzed for dioxins/furans. The spring water samples were analyzed for the following: VOCs, PAHs, PCBs, explosives, and total TAL inorganics. The results indicated the following:

- Similar to the 2008 sampling event, there was a strong correlation between the presence of suspended solids and elevated inorganics concentrations. The results from filtered samples indicated that arsenic at Monitoring Well IAA-MW002 (1.83 µg/l) was the only inorganic constituent detected at a concentration above the tap water RSLs.

- The only dioxin/furan compound detected was OCDD within sample WBG-MW001. The OCDD concentration at this location was 0.249 ng/L, which is below the tap water RSL of 1.7 ng/L. These results support the hypothesis that the multiple dioxin/furan compounds detected during the 2007 sampling event were due to laboratory contamination and were not indicative of groundwater quality at the site.

- A total of five VOCs (acetone, carbon disulfide, chloroform, chloromethane, and MTBE) were detected in isolated ground water samples. The detections were generally at very low concentrations. Chloroform detected at WBG-Spring001 was the only VOC detected at a concentration above the tap water RSL.

- Five explosive constituents (nitrobenzene, PETN, tetryl, p-nitrotoluene, and 2,6-dinitrotoluene) were detected in isolated groundwater samples. Nitrobenzene detected in Monitoring Well NBG-MW003 (0.512 µg/L) was the only explosive detected at a concentration higher than the tap water RSL .

- There were no detections of PCBs in any of the groundwater samples.

RFAAP-NRU Facility-Wide Groundwater

- Four PAH constituents (anthracene, fluoranthene, phenanthrene, and pyrene) were detected in isolated groundwater samples. All of the PAH detections were several orders of magnitude below the tap water RSLs.

An HHRA was conducted to evaluate potential exposure to constituents detected in groundwater. Potential exposure of site workers was evaluated for the vapor migration pathway. The calculated risks were well below the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. Exposure of hypothetical future adult and child residents through the vapor intrusion exposure pathway yielded similar, very low results.

Exposure of hypothetical future residents and site workers to constituents in groundwater assuming the groundwater were used as a potable water supply also was evaluated in the risk assessment. These exposure scenarios were evaluated using unfiltered and filtered groundwater data to evaluate the influence of metals present as suspended solids. This assessment was performed because the groundwater at the NRU was turbid.

The excess lifetime cancer risks calculated for hypothetical future resident exposure to groundwater used as a potable water supply was 2×10^{-4}. This is slightly above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The risk drivers for cancer risk are arsenic and the dioxin and furan congeners.

The hazard index for a hypothetical adult resident was calculated to be 0.6, which was below the benchmark of 1. The hazard index or a hypothetical child resident was calculated to be 1, which is equal to the benchmark of 1.

The risk drivers for the excess lifetime cancer risk associated with the residential land use scenario are arsenic and the dioxin and furan congeners. Arsenic was detected in 1 out of the 18 filtered samples collected; and, this detection was below the MCL. The dioxin congeners were detected in several groundwater samples during the 2007 sampling event at concentrations greater than the USEPA RSLs. However, it should be noted that many of the dioxin compounds were also detected in the rinse blank associated with the 2007 sampling event which indicates a potential cross contamination issue associated with the sampling or laboratory equipment. All of the detections during the 2007 event were below the reporting limit and were qualified as estimated. The dioxin and furan congeners were not detected during the 2010 groundwater sampling event at the RFAAP-NRU which provides further evidence that the detections driving the elevated risk levels are not indicative of actual groundwater quality at the facility.

RFAAP-NRU Facility-Wide Groundwater

It is recommended that No Action be selected for groundwater at the RFAAP-NRU.

RFAAP-NRU Summary and Conclusions

11. RFAAP-NRU Summary and Conclusions

Human health and ecological risk assessments were performed for the areas of the RFAAP-NRU. The purpose of the risk assessments was to evaluate the potential current and future excess lifetime cancer risks and potential hazards to both human and ecological receptors at the site from exposure to constituents detected in soil, groundwater, surface water, and sediment at the RFAAP-NRU. Results of the assessment are summarized in table below and discussed in the following sections.

Summary of Calculated Total ELCRs and HIs for All Constituents Except Lead

Exposure Area	Receptor	ELCR	HI	Risk/Hazard Drivers
BDDT	Current Site Worker	7E-05	0.6	-
	Future Construction Worker	2E-06	1	-
	Future Resident	4E-04	0.6 adult, 5 child	Benzo(a)pyrene, Cobalt
BLA	Current Site Worker	1E-04	0.8	-
	Future Construction Worker	7E-06	3	Copper
	Future Resident	1E-03	1 adult, 12 child	Benzo(a)pyrene, Aroclor 1254, Copper, Cobalt
IAA	Current Site Worker	1E-04	1	-
	Future Construction Worker	6E-06	3	*
	Future Adult Resident	5E-04	1 adult, 13 child	2,4-DNT, Aroclor 1254, copper, cobalt
RY	Current Site Worker	1E-04	0.4	-
	Future Construction Worker	5E-06	0.7	-
	Future Resident	3E-04	0.6 adult, 3 child	Pentachlorophenol, cobalt
WBG	Current Site Worker	1E-05	0.4	-
	Future Construction Worker	5E-07	0.5	-
	Future Resident	5E-05	0.8 adult, 6 child	Chromium
GW	Site Worker	4E-05	0.4	-
	Future Resident	2E-04	0.6 adult, 1 child	Arsenic, Dioxins/Furans

*When segregated by target organ/critical effect, HI did not exceed 1.

Summary of Estimated Blood Lead Levels

Exposure Area	Receptor	Estimated Blood Lead Level (µg/dL)		
		Adult	Child	Fetus
		50th percentile	Range	95th percentile
BDDT	Not a COPC in this area			
BLA	Current Site Worker	4.9	–	17
	Future Construction worker	5.2	–	18
	Future Adult Resident	6.5	–	23
	Future Child Resident	–	11 - 18	–
IAA	Current Site Worker	2.8	–	10
	Future Construction	2.8	–	10
	Future Adult Resident	3.2	–	11
	Future Child Resident	–	4.4 - 8.2	–
RY	Not a COPC in this area			
WBG	Current Site Worker	2	–	7
	Future Construction	2	–	7
	Future Adult Resident	2.8	–	10
	Future Child Resident	–	2.9 – 5.5	–
GW	Not a COPC in groundwater			

In addition to the constituents identified in the tables above, asbestos present in conductive flooring material and surface soils at the BLA and IAA could potentially present a risk to current and future site workers, construction workers, and hypothetical future residents. Although asbestos as not inherently hazardous, if asbestos fibers are released to air, fibers can be inhaled and pose a risk to human health. Activity based sampling at the BLA and IAA has demonstrated that intensive soil disturbance activities in areas with high asbestos concentrations have the potential to generate levels of asbestos in air that could present potential risks to current/ future industrial receptors and hypothetical future residential receptors.

11.1 Building Debris Disposal Trench

The BDDT was formerly an ephemeral unlined natural drainage swale that channeled surface water runoff from the surrounding area towards the unnamed creek which passes through the southwestern portion of the RFAAP-NRU. An approximately 600-ft long section of the drainage swale was utilized for the disposal of miscellaneous building debris derived from the dismantling of various structures at the RFAAP-NRU. The building debris consisted of concrete, wood, and rusted and broken drums of a black, tarry substance believed to be roofing tar.

RFAAP-NRU Summary and Conclusions

Samples collected from the trench indicated that PAHs were present in soils underlying the debris at concentrations above applicable screening levels. Site restoration activities were performed at the BDDT in 1998 as part of a remedial investigation that included the removal of all building debris and any visibly stained soil from the trench. The excavated material was replaced with clean fill and the trench was lined with a geotextile fabric and filled with riprap to minimize the potential for erosion. The site restoration activities mitigated the source area and potential exposure pathways along the trench; therefore, subsequent investigations focused on soil, sediments, and surface water, downgradient of the trench.

Sampling activities performed at the BDDT between 1998 and 2008 focused on the areas downslope of the trench that may have been affected by the transport of constituents prior to the site restoration activities. These areas included an open area between two hills at the downgradient reach of the trench and an unnamed stream located further downslope. Based on the physical characteristics of the site, the stream and the open area downgradient of the former disposal area would have been natural depositional areas for media (i.e., soil and debris particles) that may have washed out of the trench prior to the site restoration activities. The open area is heavily vegetated with tall grasses and has a gentle slope towards the downgradient stream. Bedrock is present at approximately 5 ft bgs throughout the BDDT Analyte classes included during the various phases of investigation at the BDDT have included explosives, pesticides, herbicides, PCBs, PAHs, SVOCs, VOCs, and inorganics.

PAHs were the most frequently detected constituents in soil within the open area downgradient of the former disposal area. PAHs were detected at concentrations above initial screening levels in 34 of the 55 surface soil samples and in 6 subsurface soil samples. The delineation of the PAHs was completed during the 2008 sampling event which defined the outer edges of the PAH detections in surface soil. The 2008 sampling event also confirmed that the subsurface PAH detections are confined to a small area immediately downgradient of the end of the former disposal area and only extend to a depth of approximately 4 ft bgs. PAH detections are not expected to extend any deeper due to the presence of shallow bedrock throughout the BDDT area.

Sediment sampling indicates that the residual PAHs present in the surface soils within the open area downslope of the BDDT are not resulting in continued releases of PAHs to the creek. The only other constituents detected in sediment at concentrations above applicable screening levels were iron and manganese, which were only detected at elevated concentrations in one sample in 1998.

The surface water data from the stream have indicated that no PAHs have been detected at concentrations above tap water RSLs. The pesticide dieldrin was detected at a concentration above the tap water RSL in two samples. The VOCs bromodichloromethane and chloroform were detected above the tap water RSL in one sample. Thallium was also detected above the tap water RSL in two samples. The isolated occurrences of these detections, and the fact that dieldrin, bromodichloromethane, chloroform, and thallium were not identified as COCs for the BDDT soils indicate that the BDDT area is not resulting in continued releases of these constituents. It should also be noted that dieldrin was also detected in surface water samples collected from the unnamed stream in 2002, far upstream of the BDDT; including, a sample collected where the stream first enters the RFAAP-NRU.

An HHRA was conducted to evaluate exposure to COCPs in surface soil, combined surface and subsurface soil, sediment, and surface water for site workers, construction workers, hypothetical adult residents, and hypothetical child residents under both current and future land-use conditions. The HHRA considered data collected from the entire BDDT site as well as a second scenario that only included data collected from the rip rap covered portion of the site. The calculated excess lifetime cancer risks and hazards were within the USEPA's target risk range of 1×10^{-6} to 1×10^{-4}, and less than or equal to the hazard index of 1,for the industrial land use scenarios. Under the future resident scenarios the ELCR was found to exceed 1×10^{-4} due to benzo(a)pyrene in surface soils. Hazards also exceeded 1 for the child resident due to exposure to the maximum concentration of cobalt in subsurface soil. However, it should be noted that with the exception of the single maximum detection of cobalt, all other cobalt detections were within established background levels for the RFAAP facility. Therefore, it is likely that the isolated elevated cobalt detection is related to natural conditions rather than historical activities at the BDDT.

A SLERA and BERA were completed for the BDDT, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that adverse effects are not expected for wildlife at the BDDT.

Based on the potential residential risks associated with the benzo(a)pyrene in surface soil located downgradient of the trench and in the soil located under the rip rap covered portions of the trench, it is recommended that a FS be conducted to evaluate the available CERCLA response actions for the site. The response action alternative analysis will include an evaluation of potential actions to reduce risk to levels acceptable for residential use of the property, as well as options for maintaining the industrial use of the property.

11.2 Bag Loading Area

The BLA is a former powder bag loading facility that operated from 1941 through 1943. The facility included a total of ten buildings that were connected by elevated walkway platforms. Seven of the buildings contained a conductive flooring material that covered the concrete slab floors. Samples of the conductive flooring material indicate that it contained asbestos and several different metals. All process equipment, wooden roofs, and wooden walls have been removed from the buildings, leaving only concrete slabs and walls in place. Removal of the building wall and roofs has exposed the conductive flooring to weather, causing it to degrade and begin to break away from the underlying concrete. In many cases, the flooring has degraded into a red powder-like material and washed onto the surrounding soils.

Environmental investigations conducted at the BLA between 1997 and 2009 focused on evaluating the effects that the deteriorating conductive flooring material and historical site operations have had on the soils surrounding the BLA buildings. Soil samples were also collected at former electrical transformer locations, near area walkways, and from area drainage ditches. Sediment and surface water samples were collected from the unnamed stream located to the north of the BLA to evaluate the potential for constituents to have migrated from the site. Water and sediment samples were also collected from an underground utility vault and former elevator shaft in Building 405. Laboratory analyte classes varied between the investigation activities but have included explosives, herbicides, pesticides, PAHs, PCBs, VOCs, SVOCs, TAL inorganics, asbestos, TCLP-inorganics, and lead-based paint analysis. An extensive soil sampling program was also conducted in 2008 that included screening 192 soil samples around BLA buildings for lead using XRF. An activity-based sampling program was also conducted in 2009 to characterize potential risks associated with asbestos in soil.

The primary constituents of concern identified during the investigation at the BLA are associated with the deteriorating conductive flooring in the existing structures. Inorganics, including arsenic, barium, cadmium, cobalt, copper, lead, and zinc have been detected in surface soil samples collected around the buildings. Lead and copper, which are believed to have been primary components of the conductive flooring material, were the most frequently detected constituents at concentrations above applicable industrial and residential RSLs. The 2008 sampling activities confirmed that the inorganics concentrations above applicable RSLs and/or background levels are generally limited to surface soils immediately adjacent (i.e. within 1 to 5 ft) to buildings with conductive flooring material; although, the elevated concentrations extend up to 10 ft from buildings in a few isolated areas. Subsurface soil sampling activities at the BLA have not identified any of the inorganics associated with the flooring material at concentrations above the applicable RSLs. Samples collected from BLA drainage ditches have also indicated that the concentrations of inorganic constituents were within background levels. The subsurface soil and drainage ditch sampling results indicate that the mobility of these constituents is very limited. The only inorganics detected at concentrations above applicable RSLs and background inorganics concentrations in subsurface soil were aluminum (2 samples) and iron (1 sample).

PAHs, which are possibly associated with the flooring material and other building materials used at the BLA, are also present at concentrations above RSLs in surface soils around the BLA buildings and former elevated walkway corridors. Concentrations of PAHs did not exceed residential RSLs in subsurface soil samples at the BLA or in drainage ditch samples.

Asbestos, another component of the conductive flooring and other BLA building materials, has been identified in surface soils surrounding the BLA buildings. The highest concentrations of asbestos in soil are confined to surface soils located immediately adjacent to the buildings with conductive flooring (i.e., within 1-ft of the building pads). The asbestos concentrations in some of the areas adjacent to the buildings are above 1% by weight. While asbestos fibers were detected in surface soil samples collected at distances greater than 5-ft from site buildings, the concentrations were typically less than 0.1% by weight. Activity based air sampling conducted adjacent to Buildings 404 and 411 confirmed that intensive disturbance of the soils immediately adjacent to the buildings has the potential to generate measureable airborne asbestos at concentrations above industrial and residential AALs.

Isolated detections of Aroclor 1254 were detected in surface soils near two former pole-mounted transformer locations at the BLA. PCBs have not been detected in sediments or surface water samples at the BLA, further supporting the theory that constituents are not migrating from the BLA.

Sediment and surface water samples were collected from two locations in the unnamed stream that passes to the north of the BLA during the 2002 site investigation.

Dieldrin was detected at a concentration above the tap water RSL in one surface water sample from the unnamed creek. However, dieldrin was also detected in other surface water samples collected from the unnamed stream in 2002, upstream of the BLA; including a sample where the unnamed stream first enters the RFAAP-NRU. No other constituents were detected in stream surface water at concentrations above applicable tap water RSLs.

Water samples collected from two utility vaults identified at the BLA contained arsenic at concentrations above the tap water RSL. No other constituents were identified in the vault water samples at concentrations above applicable RSLs.

An HHRA was conducted to evaluate exposure pathways for site (maintenance) workers, construction workers, adult residents, and child residents under both current (maintenance workers) and hypothetical future land-use conditions.

The potential cumulative risk for site workers exposed to surface soil and sediment at the BLA under current and future land-use conditions was at the high end of USEPA's target risk range of 1×10^{-6} to 1×10^{-4} for health protectiveness at Superfund sites (USEPA, 1990). The potential cumulative HI for site workers was less than the benchmark of 1.

The potential cumulative risk for construction workers were within the USEPA's target risk range of 1×10^{-6} to 1×10^{-4} for health protectiveness at Superfund sites (USEPA, 1990). However, the potential cumulative HI for construction workers was above the benchmark of 1. When the HI was segregated into target site and critical effects, hazards were above the benchmark of 1 for the gastrointestinal tract due to the presence of copper.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water was greater than the USEPA target risk range of 1×10^{-6} to 1×10^{-4}, due to the presence of benzo(a)pyrene. The total cumulative HI for hypothetical future adult residents is 1, which is equal to the benchmark of 1. The total cumulative HI for hypothetical future child residents is 12, which is greater than the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were above the benchmark of 1 in the central nervous system, whole body, and immune system, in the gastrointestinal tract, and in the eyes, nails, hair, and skin, due to the presence of Aroclor 1254, copper and cobalt.

Lead was also a constituent of potential concern for each of the receptors considered in the BLA risk assessment. For the potential future industrial and residential land use scenarios, exposure to lead resulted in predicted elevated blood lead levels. Therefore, exposure to lead could result in an unacceptable risk.

Removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and wash onto the surrounding soils. Activity based sampling at the BLA has demonstrated that the soils located immediately adjacent to site buildings, where asbestos concentrations are highest (i.e., within 1 foot of building pad), have the potential to generate airborne asbestos when disturbed. The levels of airborne asbestos generated by intensive soil disturbance activities have the potential to be above AALs for the industrial exposure scenario and the hypothetical future residential exposure scenarios.

Any residual lead based paint on the concrete walls at the BLA or other possible asbestos containing building materials (i.e., pipe insulation, joint compounds, mastic, etc.) could also present a small risk for current and future site workers, construction workers, or residents. However, it should be noted that the overall extent of these materials at the site is limited.

A SLERA and BERA were completed for the BLA, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that while some of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils and some individual piscivorous mammals and birds exposed to sediment and/or surface water. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, affects of these COPECs at the population-level are unlikely at the BLA.

The environmental investigations completed at the BLA have successfully defined and delineated the extent of effects that historical operations and degrading flooring material have had on environmental media at the site with the exception of asbestos. The investigations have confirmed that the effects are generally limited to surface soils located immediately adjacent to buildings with conductive flooring, former elevated walkways, and two former transformer locations. The results of the HHRA activities indicated that unacceptable risks and hazards are present for the industrial site worker, construction worker, and hypothetical future residential under current and future land use scenarios. The ERA activities indicated the potential for risks to individual ecological receptors, although no adverse population-level effects would be expected due to the limited areal distribution of these constituents. Although not evaluated in the risk assessment, asbestos in the remains of other building materials (e.g. pipe insulation, mastic, joint compound, etc.) and residual lead -based paint on the concrete walls could also present a potential risk to current and hypothetical future receptors. An FS is recommended to assess potential remedial alternatives to mitigate the risks and hazards associated with the site soils, conductive flooring material, and other building materials.

11.3 Igniter Assembly Area

The IAA was formerly used for igniter assembly operations and the shipping and receiving of materials. Approximately 36 buildings were located within the IAA which were connected by raised concrete walkways, gravel paths, and paved roads. Site reconnaissance activities have concluded that 29 of the buildings at the IAA contained a conductive flooring material similar to that used at the BLA. Like the BLA, all wooden roofs and walls have been removed from the IAA buildings. Exposure to the weather has caused the conductive flooring material to deteriorate into a red powder like substance and wash off onto surrounding soils.

Environmental investigations conducted at the IAA between 1997 and 2008 focused on evaluating the effects that the deteriorating conductive flooring material and historical site operations have had on the soils surrounding the IAA buildings. Soil samples were also collected at former electrical transformer locations, and from area drainage ditches. A water sample was also collected from an underground utility vault. Laboratory analyte classes varied between the investigation activities but have included explosives, herbicides, pesticides, PAHs, PCBs, VOCs, SVOCs, TAL inorganics, asbestos, TCLP-inorganics, and lead-based paint analysis. An extensive soil sampling program was also conducted in 2008 that included screening 475 soil samples around IAA buildings for lead using XRF. An activity-based sampling program was also conducted in 2009 to characterize potential risks associated with asbestos in soil.

The primary constituents of concern identified during the investigation at the IAA are associated with the deteriorating conductive flooring in the remains of the former IAA buildings. Inorganics, including, arsenic, barium, cadmium, cobalt, copper, iron, lead, mercury, nickel, and zinc have been detected in surface soil samples collected around the IAA buildings. Lead and copper, which are believed to have been the primary components of the conductive flooring material, were the most frequently detected constituents at elevated concentrations. The 2008 sampling activities confirmed that the elevated inorganics concentrations are generally limited to surface soils (i.e., 0-1 ft bgs) immediately adjacent to (i.e. within 1 to 5 ft of) buildings with conductive flooring material; although, the elevated concentrations extend up to 15 ft from several buildings in the southern portion of the IAA. Subsurface soil sampling activities at the IAA have indicated that the elevated inorganics concentrations associated with the flooring material are generally confined to the interval from 0 to 1 ft bgs. Only two subsurface soil samples collected from 1 to 2 ft bgs next to Building 504 had flooring related inorganics constituents at concentrations above applicable screening levels and background concentrations. Deeper samples collected from this and other areas of the site did not contain any flooring related inorganics at concentrations above applicable RSLs and background levels. Aluminum, which is not related to the flooring material, was detected in two subsurface soil samples at concentrations above the residential RSL and slightly above background levels. The results of TCLP analysis of soil samples collected around IAA buildings in 2008 indicated that no constituents were present at concentrations above applicable TCLP screening levels.

Asbestos, another component of the conductive flooring and other IAA building materials, has been identified in surface soils surrounding IAA buildings. The highest concentrations of asbestos in soil are confined to surface soils located immediately adjacent to the buildings with conductive flooring (i.e., within 1 foot of building pad). While asbestos fibers were detected in surface soil samples collected at distances greater than 5-ft from site buildings, the concentrations were typically less than 0.1% by weight.

Aroclor 1254 and Aroclor 1260 were detected at concentrations above applicable screening levels in a few isolated surface soil samples collected adjacent to several buildings in the IAA. Several SVOC/PAH compounds were also detected in isolated surface soil samples at concentrations above applicable RSLs.

No explosives, herbicides, pesticides, or VOCs were detected in IAA soils at concentrations above applicable RSLs.

Soil/sediment samples were collected from IAA drainage ditches to evaluate whether constituents were being transported from the building areas. The analytical data indicated that several of the samples collected adjacent to area roadways contained PAHs at concentrations approaching, and in some cases above, applicable RSLs. As

PAHs were only present in isolated surface soil samples at the IAA, these detections can likely be attributed to the asphalt from the paved road. Lead was also detected at concentrations above applicable RSLs in two samples collected from ditches that transport water from the main building area of the IAA. Additional sampling conducted in these drainage ditches during the 2008 site investigation indicated that the lead concentrations were only slightly above background and were below applicable screening levels; therefore, the previous lead detections in these areas were likely isolated and not indicative of transport from the conductive floors.

One water sample collected from an underground utility vault did not contain any constituents at concentrations above tap water RSLs. No other surface water samples were collected during the IAA investigation, as there are no surface water bodies in the vicinity of the IAA. The drainage ditches at the IAA only carry water during heavy rainfall events.

An HHRA was conducted at the IAA to evaluate potential exposures associated with site constituents to humans. Site worker exposures to surface soil and sediment were evaluated under current and future land-use conditions; and construction worker, adult resident, and child resident exposures to total soil and sediment were evaluated under future land-use conditions.

The soil and sediment COPCs were evaluated for direct contact. VOCs identified as COPCs in the IAA were also evaluated for inhalation via vapor migration into buildings. Two VOCs, 3-octanone and d-limonene, do not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area.

A current or future site worker could be present at the IAA area, and could be exposed to surface soil or sediment. The total cumulative ELCR for site workers exposed to surface soil and sediment is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is equal to the benchmark of 1. Lead was also evaluated as a COPC, although the results are reported differently than those for the other COPCs. The predicted worker blood lead levels were below the benchmark and the predicted fetal lead level was equal to the benchmark.

A hypothetical future construction worker could be present at the IAA area, and could be exposed to combined surface and subsurface soil. The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the IAA was within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is greater than the benchmark of 1. However, when the hazard index was segregated by target organ or critical effect, all of the HIs were below the benchmark. The predicted worker blood lead levels were below the benchmark and the predicted fetal lead level was equal to the benchmark.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil and sediment at the IAA is 5×10^{-4}, which is slightly above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The primary contributor to risk estimates is 2,4-dinitrotoluene in soil. The total cumulative HI for hypothetical future adult residents is 1, which is equal to the benchmark. The total cumulative HI for hypothetical future child residents is 13, which is above the benchmark of 1. When the HI was is segregated by target site and critical effects, hazards were greater than the benchmark of 1 due to the presence of Aroclor 1254, cobalt, and 2,4-dinitrotoluene. The predicted adult resident blood lead levels were below the benchmark of 10 µg/dl, and the predicted fetal lead level was slightly greater than the benchmark.

The majority of the risk drivers for the IAA were only sporadically detected. One surface soil sample and one subsurface soil sample had Aroclor 1254 concentrations greater than 1 mg/kg, which is the Toxic Substances Control Act (TSCA) soil concentration for residential exposure. 2,4-Dinitrotoluene was detected in only two of thirty-six samples with the two detections collected from two depths at the same boring location. No other detections of this constituent were confirmed during subsequent sampling events. Finally, only the single maximum concentration of cobalt (422 mg/kg) fell outside of the background concentration range of 5.9 mg/kg to 130 mg/kg. As such 2,4-dinitrotoluene, cobalt and Aroclor 1254 are not considered primary drivers for remediation at the site.

Removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and wash onto the surrounding soils. Activity based air sampling conducted at IAA Building 8102-1 has demonstrated that intensive soil disturbance activities in areas with high asbestos concentrations (i.e., immediately adjacent to buildings where conductive flooring has washed off the building pads) have the potential to generate measurable concentrations of asbestos in air. In fact the concentrations in air for the activity based sampling adjacent to Building 8102-1 were above the AALs for the industrial exposure scenario and the hypothetical future residential exposure scenarios.

While not evaluated in the risk assessment any residual lead based paint on the concrete walls at the IAA or other possible asbestos containing building materials (i.e., pipe insulation, joint compounds, mastic, etc.) could also present a small risk to current and future receptors. However, it should be noted that the overall extent of these materials at the site is limited.

A SLERA and BERA were completed for the IAA, to evaluate surface soil and sediment for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the aquatic and terrestrial food chain models indicate that some of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils and some individual piscivorous mammals and birds exposed to sediment and/or surface water. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, effects of these COPECs at the population-level are unlikely at the IAA.

The environmental investigations completed at the IAA have successfully defined and delineated the extent of impacts that historical operations and degrading flooring material have had on environmental media at the site. The investigations have confirmed that the effects are generally limited to surface soils located immediately adjacent to buildings with conductive flooring. The results of the HHRA activities indicated that asbestos in soil is the only risk driver for the industrial exposure scenario. Under the hypothetical future residential exposure scenarios, asbestos, lead and Aroclor 1254 were all identified as potential risk drivers. There is also an active source (conductive flooring) that still has the potential to release constituents into the environment. The ERA concluded that the potential adverse affects to ecological receptors is limited due to the limited spatial distribution of constituents.

An FS is recommended to assess potential remedial alternatives to mitigate the risks and hazards associated with the site soils, conductive flooring material, and other building materials at the IAA.

11.4 Rail Yard

The RY encompasses an open area approximately 3,200 ft long by 350 ft wide (approximately 39 acres) in the central portion of the RFAAP-NRU. The RY was used for loading and unloading rail cars and the temporary storage of rail cars.

Environmental investigations conducted at the RY between 1997 and 2002 included the collection of surface soil and subsurface soil samples from various areas of the site, including: along the railroad tracks and spurs; adjacent to transfer platforms and former building locations; near former electrical transformer locations; and in area drainage pathways. Surface water and sediment samples were also collected from the pond and streams located in the vicinity of the RY. Laboratory analyte classes varied between the investigation activities but have included explosives, herbicides, pesticides, PAHs, PCBs, VOCs, SVOCs, and TAL inorganics. The investigation activities were conducted to evaluate whether the RY was affected by historical operations at the site, and if so were constituents of concern migrating away from the site.

The extensive soil sampling activities at the RY indicated that there were limited sporadic detections of compounds at concentrations above applicable screening levels. However, there was no pattern of spatial distribution or indication of source areas. PCBs were not detected at any of the former transformer locations. Subsurface soil sampling activities also indicated no evidence of significant constituent concentrations in the subsurface. Offsite surface water and sediment gave no indication of being affected by constituents migrating from the site. Based on the compiled data from the various phases of investigation at the site, there do not appear to be significant elevated concentrations of contaminants at the RY.

The results of the human health risk assessment indicate that use of the RY for industrial use should not result in unacceptable risks to potential receptors. Although the calculated ELCR and HI for the residential land use scenarios were above the applicable thresholds, the risks and hazards were due to pentachlorophenol and cobalt, respectively. Pentachlorophenol, which is known to be a wood preservative used in utility poles, was detected in a single sample at a concentration above applicable screening levels. This sample was collected at a former utility pole location and was not detected in samples collected from other areas of the site. Due to the extremely limited extent of the detection, this constituent is not considered to be of any risk to site receptors. Likewise the elevated HI was attributed to a single cobalt detection with a concentration slightly above background levels. Therefore, cobalt is not considered to be a risk to any site receptors.

A SLERA and BERA were completed for the RY, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that a few of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils and some individual piscivorous mammals and birds exposed to sediment and/or surface water, if all exposure assumptions are met. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, adverse affects at the population level are considered unlikely for the shrew (or other insectivorous mammals) and the robin (or other insectivorous birds) exposed to the constituents at the RY.

The investigation activities performed at the Rail Yard did not identify any significant evidence of potential adverse affects to environmental media at the site as a result of historic operations. The results of the human health risk assessment indicate that use of the Rail Yard for residential or industrial uses should not result in unacceptable risks to potential receptors. The ERA also indicated that no adverse impacts would be expected to ecological receptors on a population level. Therefore, no action is recommended for this site.

11.5 Western Burning Ground

The WBG was formerly used as a burning ground to decontaminate explosives contaminated material and to dispose of excess and off-spec explosives/energetics during historical site operations. The main burn area was approximately 170 ft long by 100 ft wide and is surrounded on three sides by an approximately 4 ft high earthen berm. A dirt road runs parallel to the open side of the former burn area, leading north to Alger Road, and south to the top of a steep slope above an unnamed pond. The dirt road was reportedly constructed on top of an ashy layer of material extending from the burning ground at the time of the pond construction. The pond was constructed during the early 1990s and is fed by Wiggins Spring at the northwest (upgradient) end of the pond. The pond also collects runoff from the surrounding area through a series of storm water ditches/culverts. The WBG is no longer active.

Site characterization activities performed at the WBG from 1997 through 1999 indicated the presence of an ashy layer of material throughout the burn area and elevated concentrations of inorganics and PAHs in burn area soils. A test pitting program completed in 1999 effectively removed all of the soils containing elevated constituent concentrations from the former burn area; therefore, the burn area no longer poses an environmental concern. Samples collected in 1999 from the berms surrounding the former burn area had no constituents above applicable screening levels or background inorganics concentrations; therefore, the berms do not appear to have been affected by operations at the site.

Investigations performed at the WBG between 1998 and 2008 have focused on characterizing and delineating constituent detections outside of the former burn area. Areas that have been investigated have included the access road on the northwest side of the burn area; surface and subsurface soils located downgradient from the burn area; sediments and surface water in the unnamed pond; sediments and surface water in the unnamed creek downgradient of the pond; and a former transformer location. Analyte classes included in the WBG investigation have included VOCs, SVOCs, PAHs, PCBs, pesticides, herbicides, dioxins/furans, explosives, and inorganics.

One of the primary areas of investigation at the WBG has been the dirt access road which runs along the open side (northwestern side) of the former burn area. During the course of investigation at the site, an ashy layer of material was identified in the subsurface (approximately 2-4 ft bgs) under the road that was very similar to the ashy soils that had been present in the burn area. With the exception of one subsurface soil sample at the end of the access road no constituents were detected above applicable screening levels in any of the surface or subsurface soil samples in this area (including within the ashy layer of material).

Surface and subsurface soil samples were also collected downgradient (northwest, west, and south) of the burning ground and road to evaluate the potential for constituents to have migrated outside the burn area. The results from these areas indicated:

- Despite the fact that the former burning ground operations were used to decontaminate and dispose of materials that had been in contact in explosive/energetic compounds, explosives were not found to be a concern at the site. Only one explosive compound was ever detected during the course of sampling at a single location. Penterythritol tetranitrate was detected at a concentration of 0.11 mg/kg at surface soil at WBGSB24.

- Seventeen different PAHs were detected in surface and subsurface soil outside of the former burn area. PAHs were detected at concentrations above applicable RSLs in two surface soil samples collected from a small drainage pathway located to the west of the former burn area. This drainage pathway receives runoff from the surrounding area and paved roads, and the PAHs detected in these samples are very similar to those observed in samples collected from drainage ditches located near roadways throughout the RFAAP-NRU.

- No PCBs were detected in the soil sample collected at the former transformer location.

The pond sediment sampling activities indicated that lead and chromium were present at concentrations above background levels and applicable RSLs in samples collected in an isolated 2,100 ft^2 area near the northern bank of the pond. The outer perimeter of the area containing the lead and chromium concentrations above applicable screening levels has been delineated through the collection of multiple samples for both laboratory analysis and XRF field screening. PAHs were detected at concentrations above residential RSLs in three samples located in the northwestern portion of the pond. These samples were located near points where surface water drainage ditches enter the pond. The explosive nitroglycerine was detected in one pond sediment sample at a concentration above the residential RSL. Several dioxins/furans were also detected in pond sediment samples; however the all detected constituents were below residential RSLs.

A total of six sediment samples were collected from the stream downgradient of the outfall of the unnamed pond. Arsenic and iron were detected in one sample at concentrations above background and applicable screening levels. PAHs were also detected at concentrations above applicable screening levels in one sediment sample. A second sample collected at this location in 2008 indicated that only benzo(a)pyrene was present at a concentration above a residential screening level. No other constituents were detected at concentrations above applicable RSLs.

Surface water samples collected from the pond and the unnamed stream indicated the following:

- Lead was detected at concentrations above the USEPA tap water RSL in four surface water samples from the pond. These samples were all collected in the area where the elevated concentrations of lead were detected in sediment. Lead was not detected above applicable screening levels in any samples from the stream.

- Arsenic was detected above the tap water RSL in two samples collected from the pond in 1999. Arsenic was not detected in any other samples collected from the pond or from the stream throughout the remainder of the investigation.

- Iron, manganese, and thallium were detected above the tap water RSL values in single samples collected from the stream near the pond outfall. The herbicide MCPP was also detected in one sample from the stream at a concentration above the tap water RSL.

- The pesticide dieldrin was detected in two samples at concentrations above tap water RSLs. One sample was in the unnamed stream that flows through the RFAAP-NRU, upstream of the confluence with the stream from the WBG. This indicates the possible presence of a dieldrin source somewhere off of the facility.

- Perchlorate and tetrachloroethene were also detected in one sample at concentrations above tap water RSLs. These constituents were not detected in any other surface water, sediment, or soil samples at the WBG.

- The VOC chloroform was detected in two pond water samples and two stream samples during the 2002 investigation at concentrations above the tap water RSL but well below its MCL.

The HHRA evaluated potential current exposure of site workers to surface soil, surface water, and sediment, potential future exposures of construction workers to total soil and potential future adult and child resident exposure to total soil, surface water, sediment, and fish caught in the pond at the WBG. The soil, sediment, and surface water COPCs were evaluated for direct contact. In addition, a scenario was evaluated that specifically considered exposure to sediment during participation in the semi-annual fishing rodeo, and risks to all potential future receptors were evaluated in the event that the pond were drained and current sediments became eligible for direct contact in the same frequency, intensity, and duration as soils.

VOCs identified as COPCs in the WBG were also evaluated for inhalation via vapor migration into buildings. One VOC, d-limonene, was identified as a soil COPC at the WBG, but since it does not have identified inhalation toxicity value, this exposure pathway was not evaluated quantitatively. Potential risks and hazards for site workers and construction workers, including exposure to lead, under current industrial land use conditions were within generally acceptable levels and benchmarks. Under a hypothetical future residential land use, potential hazards associated with chromium in sediment were slightly greater than the benchmark for the child resident. Potential risks associated with exposure to lead in the pond sediments could result in adverse health effects. No other scenarios evaluated resulted in an unacceptable risk level. The residential risk findings are applicable to both current land use conditions and those that would result if the pond were drained and current sediments became part of the soil eligible for direct contact exposures.

Based on the results of the risk assessment, it is unlikely that industrial use of the property would result in adverse health effects. For the residential exposure scenarios, exposure to lead in sediments may pose an adverse health effect if the exposure assumptions are different than actual exposures. Also, exposure to chromium in sediments may pose a slightly elevated hazard to children wading in the pond. The maximum chromium sediment concentration of 15,400 mg/kg is well above the background range.

A SLERA and BERA were completed for the WBG, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial food chain model indicate that some of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils and some individual piscivorous mammals and birds exposed to sediment and/or surface water. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, adverse affects of these COPECs at the population-level are unlikely at the WBG.

Similarly, the results of the sediment and surface water evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the aquatic food chain model indicate that adverse effects are not expected for aquatic life exposed to bioaccumulative COPECs in sediment and/or surface water at the WBG.

The environmental investigations completed at the WBG have successfully delineated the nature and extent of elevated constituent concentrations in soils, sediments, and surface water. The results of the investigation and the corresponding risk assessment activities indicated that the potential risks associated with the site are within acceptable ranges for industrial use of the site. Under a potential future residential use scenario, risks were slightly above the acceptable range due to the presence of chromium and lead in a small area of pond sediments. Based on the potential residential risks associated with the lead and chromium in the pond sediments, it is recommended that a FS be conducted to evaluate potential remedial options for the pond sediments.

11.6 Groundwater

The groundwater investigation activities at the RFAAP-NRU have included the installation of 11 groundwater monitoring wells and groundwater sampling events in 2007, 2008, and 2010. In addition to sampling all of the monitoring wells, the 2008 and 2010 events also included the collection of samples from 4 springs located within the boundaries of the RFAAP-NRU. The spring samples were collected because the function of springs as groundwater discharge points for convergent conduit networks in the karst system makes them ideal locations for screening for groundwater quality.

The 2007 groundwater sampling event included the collection of groundwater samples from 11 monitoring wells located throughout the RFAAP-NRU. The wells were installed at, or in the vicinity of, the Study Areas at the RFAAP-NRU due to the known presence of constituents in surface soil. Four wells are located in the vicinity of the IAA, three wells are located at the WBG, two wells are located at the BLA, and two wells are located at the NBG. The monitoring wells were analyzed for a full suite of parameters including dioxins/furans, explosives, herbicides, pesticides, PAHs, PCBs, SVOCs, VOCs, and inorganics. The results indicated the following:

- No herbicides, pesticides, PCBs, SVOCs, or PAHs were detected in any of the groundwater samples.

- The VOC chloroform was detected in one sample (WBGMW01) at a concentration above the tap water RSL, but well below its MCL. Chloroform was not detected at any other sample locations

- Several dioxin/furan related compound were reported at low concentrations in all of the groundwater samples. Despite the low concentration, some of these constituents were above the tap water RSLs. However, the detected constituents were qualified due to the detection of dioxins and furans in laboratory blank samples. Dioxins and furans were not identified as primary COCs in soil at any of the Study Areas, therefore, it is unlikely that the reported detections in groundwater are associated with RFAAP-NRU.

- Several inorganic constituents were detected in all of the groundwater samples collected during the 2007 investigation. In most cases the detected concentrations were below applicable tap water RSLs; however three samples contained constituents at concentrations above the tap water RSLs. The sample from Monitoring Well IAA-MW01had arsenic, iron, lead, and manganese at concentrations above applicable RSLs. Monitoring Well NBG-MW01 had arsenic at a concentration above the tap water RSL (note that arsenic was also detected in a laboratory blank sample associated with this sample). Monitoring Well WBG-MW01 had arsenic and lead at concentrations above the RSLs (again note that arsenic was detected in a laboratory blank sample associated with this sample).

ARCADIS conducted a groundwater sampling event at the RFAAP-NRU in 2008 to evaluate whether suspended solids and naturally occurring inorganics in soils could have contributed to the elevated inorganics concentrations observed during the 2007 groundwater sampling event. ARCADIS utilized low flow sampling techniques to sample all eleven groundwater monitoring wells at the facility to reduce the presence of suspended solids in the groundwater samples. When the low flow sampling techniques were unable to lower turbidity readings below a threshold of 40 NTU, samples were collected for both total and filtered laboratory analysis. The results of this sampling event indicated the following:

- There was a strong correlation between the presence of suspended solids and elevated inorganics concentrations. Inorganics concentrations were typically lower in samples with lower turbidity readings. Samples that were analyzed after filtering also illustrated a large drop in inorganics concentrations.

- The unfiltered samples collected at monitoring wells IAA-MW01 and NBG-MW02 had concentrations of aluminum, arsenic, iron, lead and manganese at concentrations above applicable tap water RSLs. These samples, which were the only wells sampled with inorganics concentrations above applicable RSLs, both had turbidity readings above 1,000 NTU. The analytical results from the filtered samples at these locations indicated a significant drop in inorganics concentrations and no constituents were detected at concentrations above applicable RSLs.

The 2008 groundwater sampling event also included the collection of four spring water samples. One sample was collected from Wiggin's Spring at the head of the WBG pond, one sample was collected from the unnamed spring at the head of the RY pond; the other two spring samples were collected from unnamed springs located in the northeastern portion of the RFAAP-NRU. The samples were analyzed for inorganics and PAHs. The samples had very low turbidity and indicated that several inorganics were present at concentrations below applicable tap water RSLs. The presence of these metals in groundwater should be expected due to naturally occurring inorganics in soil at the RFAAP-NRU. The PAH naphthalene was detected in the samples from the WBG and RY springs. Phenanthrene was also detected at the RY spring. The concentrations of naphthalene and phenanthrene were several orders of magnitude below applicable tap water RSLs.

The 2010 groundwater sampling event was conducted at the request of VDEQ to provide an additional data set for risk assessment purposes. This sampling event was similar to the 2008 sampling activities in that all eleven groundwater monitoring wells and four spring water sample locations were sampled using low-flow sampling techniques. The samples were analyzed for VOCs, PAHs, total metals, dissolved metals, explosives, PCBs, and dioxins/furans. The results from the 2010 sampling event indicated the following:

- Only one dioxin compound, OCDD, was detected in the samples. This constituent was detected in a single monitoring well, WBG-MW001, at a concentration well below the tap water screening RSL. This result confirms that dioxins and furans detected during the 2007 sampling event were likely due to laboratory blank contamination and should not be considered constituents of concern for groundwater at RFAAP-NRU.

- As with the 2008 sampling event, there was a good correlation between the presence of suspended solids and elevated metals concentrations in the groundwater samples. Arsenic, a naturally occurring metal at the site, was the only inorganic constituent detected in the filtered groundwater samples that was present at a concentration above tap water RSLs. This detection occurred a single monitoring well (IAA-MW002)

- One explosive, nitrobenzene, was detected in a single monitoring well (WBG-MW003) at a concentration (0.512 µg/L) above the tap water RSL of 0.12 µg/L. This constituent was not detected in any other monitoring well or spring water samples during the 2010 or 2007 sampling events. No other explosives were detected at concentrations above tap water RSLs.

- Chloroform was detected in a single spring water sample (WBG-Spring001) at a concentration below the laboratory reporting limit, but above the tapwater

RSL of 0.19 µg/L. No other VOCs were detected at concentrations above applicable RSLs.

- A few PAHs (phenanthrene, pyrene, fluoranthene, and anthracene) were detected in isolated monitoring samples; however, the concentrations were several orders of magnitude lower than tap water RSLs.

- No PCBs were detected in any of the samples.

An HHRA was conducted to evaluate potential exposure to constituents detected in groundwater at RFAAP-NRU. The HHRA utilized the data collected during all three sampling events completed at the facility. The risk assessment for groundwater evaluated exposure under both industrial/site worker scenarios and residential use scenarios.

Potential exposure of site workers was evaluated for the vapor migration pathway. The calculated risks were well below the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. Exposure of hypothetical future adult and child residents through the vapor intrusion exposure pathway yielded similar, very low results.

Exposure of hypothetical future residents and site workers to constituents in groundwater assuming the groundwater were used as a potable water supply also was evaluated in the risk assessment. These exposure scenarios were evaluated using unfiltered and filtered groundwater data to evaluate the influence of metals present as suspended solids. This assessment was performed because the groundwater at the NRU was turbid.

The excess lifetime cancer risks calculated for hypothetical future resident exposure to groundwater used as a potable water supply was 2×10^{-4}. This is slightly above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The risk drivers for cancer risk are arsenic and the dioxin and furan congeners. The hazard index for a hypothetical adult resident was calculated to be 0.6, which was below the benchmark of 1. The hazard index or a hypothetical child resident was calculated to be 1, which is equal to the benchmark of 1.

The risk drivers for the excess lifetime cancer risk associated with the residential land use scenario are arsenic (which is naturally occurring) and the dioxin and furan congeners. Arsenic was detected in 1 out of the 18 filtered groundwater samples collected; and, this detection was below the federal drinking water MCL. The apparent risks associated with the dioxin/furan congeners are due to the detections within the 2007 data set. However, as mentioned earlier, the dioxins/furans are not believed to be indicative of actual groundwater quality at the site because the constituents were also detected in blank samples during the 2007 sampling event and are likely due to laboratory contamination. This was confirmed by the lack of dioxins and furan detections during the 2010 groundwater sampling event. In summary, arsenic and the dioxin/furan constituents are not considered to be drivers for remediation at the site.

No Action is recommended for groundwater at the RFAAP- NRU.

Zinc	7440-66-6	2.30E+03	n	3.10E+04	nm		1.10E+00	n	

Notes:
COPC = Constituent of Potential Concern
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Regional screening levels were from USEPA (2008a).

The screening levels used were risk screening levels for the residential scenario from USEPA (2008a). Screening levels based on non-cancer effects were adjusted by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n SL < 100X c SL; ** = where n SL < 10X c SL; n = noncancer; m = Concentration may exceed ceiling limit;
s = Concentration may exceed saturation concentration (Csat).
< The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.

[b] Adjusted soil screening levels were used to assess soil and sediment at the NRU.
[c] Adjusted tap-water screening levels were used to assess surface water and groundwater at the NRU.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration
B (Organics)	Constituent was detected in
J	Constituent concentration
K	Estimated concentration
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration
B (Organics)	Constituent was detected
J	Constituent concentration
K	Estimated concentration
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

µg/L	Micrograms per liter.
[a]	USEPA Regional Screening Levels (USEPA 2008a). Adjusted tap-water screening levels used to assess surface water at the NRU.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{max}	Concentration may exceed ceiling limit.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
24,400	Highlighted value indicates constituent concentration is above adjusted tap water RSL.

Total Organic Carbon	- -	- -	- -	mg/kg	17,300 K	12,500 K	NA	NA

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per
[a]	USEPA Regional Screening Levels (USEPA 2008a).
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).

µg/L	Micrograms per liter.
[a]	USEPA Regional Screening Levels (USEPA 2008a). Adjusted tap-water screening levels used to assess surface water at the NRU.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
J	Constituent concentration quanitified as estimated.
24,400	Highlighted value indicates constituent concentration is above adjusted tap water RSL.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilograms.

PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

* = Surface soil
r = Rip-rap area

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in surface soil (0-2 foot depth interval).
[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.
[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).
[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or they were known laboratory contaminants (i.e. acetone).

Notes:

CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in sediment.

[b] The screening levels used were risk screening levels for the residential scenario from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or they were known laboratory contaminants (i.e. acetone).

mg/L = Milligrams per liter.

[a] Constituent of Potential Concern.
[b] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

Notes:

– = Not available or applicable.

mg/kg = Milligrams per kilogram.

NA = Not available or applicable.

[a] Background levels for inorganics are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).

[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.

[c] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.

[d] Constituent was considered at bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment quality Assessment, Status and Needs, February 2000.

[e] Constituents with a hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were metals present at concentrations below background (max • BKGD).

Table 5-28
Baseline Level - Constituents of Potential Ecological Concern in Surface Soil (0-1 foot Depth Interval)
BUILDING DEBRIS DISPOSAL TRENCH
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:
– = Not available or applicable.
mg/kg = Milligrams per kilogram.
NA = Not available or applicable.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The refined hazard quotient (HQ) is the ratio of the EPC to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e] Constituent was considered at bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment quality Assessment, Status and Needs, February 2000.

Table 5-31
Summary of Ecological Risk Characterization Results - Terrestrial Habitat
BUILDING DEBRIS DISPOSAL TRENCH
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

– =	Not applicable.
COPEC =	Constituent of Potential Ecological Concern.
EPC =	Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration.
	EPCs marked with "m" are the maximum concentration.
LOAEL HQ =	Lowest observed adverse effect level hazard quotient.
mg/kg =	Milligrams per kilogram.
NA =	Not available.
NOAEL HQ =	No observed adverse effect level hazard quotient.
[a]	Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b]	See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
	R5: Region 5 Ecological Screening Levels (USEPA 2003e; R5).
	EcoSSL: USEPA Ecological Soil Screening Levels (USEPA 2005b; EcoSSL).
	Where readily available (i.e., EcoSSLs), the basis of the ESL is presented.
[c]	Foodchain modeling was conducted for bioaccumulative COPECs.

Table 5-32
Summary of Ecological Risk Characterization Results - Aquatic Habitat
BUILDING DEBRIS DISPOSAL TRENCH
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

– =	Not applicable.
EPC =	Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration.
	EPCs marked with "m" are the maximum concentration.
LOAEL HQ =	Lowest observed adverse effect level hazard quotient.
mg/kg =	Milligrams per kilogram.
mg/L =	Milligrams per liter.
NOAEL HQ =	No observed adverse effect level hazard quotient.
[a]	Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b]	Foodchain modeling was conducted for bioaccumulative COPECs.

mg/kg	Milligrams per killogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
J	Constituent concentration quanitified as estimated.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per killogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics indicates concentration is above facility-wide background value.

mg/kg	Milligrams per killogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quantified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics indicates concentration is above facility-wide background value.

mg/kg	Milligrams per killogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics indicates concentration is above facility-wide background value.

[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
ft	Feet.
mg/kg	Milligrams per kilogram.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per killogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics indicates concentration is above facility-wide background value.

Notes:
– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilograms.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Zinc	7440-66-6	1.25E+04	2.30E+03	nm	3.10E+04	n		2.02E+02	**YES**	no	no

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in surface soil.
[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.
[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).
[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or they were known laboratory contaminants (i.e. acetone).

Table 6-21
Selection of Constituents of Potential Concern for Combined Surface and Subsurface Soil
BAG LOADING AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Constituent	CASN	Maximum Concentration [a]	Adjusted Soil Regional Screening Level (RSL) [b]			Background Level [c]	Does Maximum Exceed RSL?		Is Constituent a Surface/ Subsurface Soil COPC? [d]
			Industrial Scenario	Residential Scenario	Surrogate		Industrial	Residential	
		(mg/kg)	(mg/kg)	(mg/kg)		(mg/kg)	(YES, no)	(YES, no)	(YES, no)

Notes:

– =	Not detected/ not analyzed/ not applicable.	NA =	Not available or not applicable.
CASN =	Chemical abstracts registry number.	RSL =	Regional Screening Level.
COPC =	Constituent of Potential Concern.	USEPA =	United States Environmental Protection Agency.
mg/kg =	Milligrams per kilogram.		

[a] Maximum concentration in combined surface and subsurface soil.

[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or they were known laboratory contaminants (i.e. acetone).

CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Constituent of Potential Concern.
[b] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

mg/kg = Milligrams per kilogram.

NA = Not available or applicable.

[a] Background levels for inorganics are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).

[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.

[c] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.

[d] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment quality Assessment, Status and Needs, February 2000.

[e] (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were inorganics present at concentrations below background (max • BKGD).

mg/kg = Milligrams per kilogram.
NA = Not available or applicable.

[a] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[b] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the sediment screening level. HQs are rounded to one significant figure.
[c] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment quality Assessment, Status and Needs, February 2000.
[d] Constituents with a hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were inorganics present at concentrations below background (max • BKGD).

Notes:
– = Not applicable.
COPEC = Constituent of Potential Ecological Concern.
EPC = Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration.
EPCs marked with "m" are the maximum concentration.
LOAEL HQ = Lowest observed adverse effect level hazard quotient.
mg/kg = Milligrams per kilogram.
NA = Not available.
NOAEL HQ = No observed adverse effect level hazard quotient.

[a] Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
R5: Region 5 Ecological Screening Levels (USEPA 2003e; R5).
EcoSSL: USEPA Ecological Soil Screening Levels (USEPA 2005b, EcoSSL).
Where readily available (i.e., EcoSSLs), the basis of the ESL is presented.
[c] Foodchain modeling was conducted for bioaccumulative COPECs.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

Asbestos												
Chrysotile	- -	- -	- -	% ASB	NA	NA	NA	NA	2.1	NA	NA	NA

mg/kg	Milligrams per kilogram
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
NA	Not Analyzed.
ND	Not Detected above laboratory detection limit.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

Table 7-6. Conductive Flooring Analytical Results, Igniter Assembly Area, 2002 US Army Corp of Engineers Sampling, Radford Army Ammunition Plant, Radford, Virginia.

mg/kg	Milligrams per kilogram.
µg/kg	Micrograms per kilogram.
µg/L	Micrograms per liter.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
ND	Not Detected.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

IAA-SE008X	0.17	08/01/08	--	24
IAA-SE009X	0.17	08/01/08	--	**40**

[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
ft	Feet.
mg/kg	Milligrams per kilogram.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
µg/kg	Micrograms per kilogram.
µg/L	Micrograms per liter.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
µg/kg	Micrograms per kilogram.
µg/L	Micrograms per liter.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
1	XRF screening value was from associated in-situ screening point (e.g. IAA-SE001X)
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
J	Constituent concentration quanitified as estimated.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

Soil Risk Assessment Dataset
Combined Surface and Subsurface Soil
IGNITER ASSEMBLY AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Constituent [a]	CASN	Frequency of Detection (FOD) [b]				Detects			Detection Limits			Maximum Location
		number of detects / number of samples			FOD %	Min (mg/kg)	-	Max (mg/kg)	Min (mg/kg)	-	Max (mg/kg)	
Vanadium	7440-62-2	137	-	139	99	10.8	-	98.4	–	-	–	50240
Zinc	7440-66-6	137	-	139	99	6	-	21800	–	-	–	SS-11

Notes:
– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in surface soil (0-2 foot depth interval).

[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or they were known laboratory contaminants (i.e. acetone).

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Constituent of Potential Concern.
[b] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

[a] Background levels for inorganics are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.
[e] Constituents with a hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were inorganics present at concentrations below background (max • BKGD).

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The refined hazard quotient (HQ) is the ratio of the EPC to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.

EPC =	Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
LOAEL HQ =	Lowest observed adverse effect level hazard quotient.
mg/kg =	Milligrams per kilogram.
NA =	Not available.
NOAEL HQ =	No observed adverse effect level hazard quotient.
[a]	Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b]	See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate. R5: Region 5 Ecological Screening Levels (USEPA 2003e; R5). EcoSSL: USEPA Ecological Soil Screening Levels (USEPA 2005b, EcoSSL). Where readily available (i.e., EcoSSLs), the basis of the ESL is presented.
[c]	Foodchain modeling was conducted for bioaccumulative COPECs.

Table 7-32

Summary of Ecological Risk Characterization Results - Aquatic Habitat

IGNITER ASSEMBLY AREA

New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

–	Not applicable.
EPC	Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
FOD	Frequency of Detection.
LOAEL	Lowest observed adverse effect level.
mg/kg	Milligrams per kilogram.
mg/L	Milligrams per liter.
NOAEL	No observed adverse effect level.
[a]	Hazard Quotients greater than one are presented in bold font.
[b]	Food Web modeling was conducted for bioaccumulative COPECs.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

µg/L	Micrograms per liter.
[a]	USEPA Regional Screening Levels (USEPA 2008a). Adjusted tap-water screening levels used to assess surface water at the NRU.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
{max}	Concentration may exceed ceiling limit.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted tap water RSL.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in surface soil (0-2 foot depth interval).
[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.
[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).
[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Table 8-16
Selection of Constituents of Potential Concern for Sediment
RAIL YARD
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Constituent	CASN	Maximum Concentration [a]	Adjusted Soil Regional Screening Level (RSL) [b]			Is Constituent a Sediment COPC? [c]
			Residential Scenario		Surrogate	
		(mg/kg)	(mg/kg)			(YES, no)
Vanadium	7440-62-2	1.10E+02	5.50E+01	n		**YES**
Zinc	7440-66-6	1.10E+02	2.30E+03	n		no

Notes:

CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in sediment.

[b] The screening levels used were risk screening levels for the residential scenario from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit;
s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Notes:
– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Constituent of Potential Concern.
[b] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

Notes:
– = Not available or applicable.
mg/kg = Milligrams per kilogram.
NA = Not available or applicable.

[a] Background levels for inorganics are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.
[e] Constituents with a hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were inorganics present at concentrations below background (max • BKGD).

[a] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[b] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the sediment screening level. HQs are rounded to one significant figure.
[c] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.
[d] Constituents with a hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT).

Notes:
– = Not available or applicable.
mg/L = Milligrams per liter.
NA = Not available or applicable.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The refined hazard quotient (HQ) is the ratio of the EPC to the surface water screening level. HQs are rounded to one significant figure.
[d] Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.

Notes:

– =	Not applicable.
COPEC =	Constituent of Potential Ecological Concern.
EPC =	Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
LOAEL HQ =	Lowest observed adverse effect level hazard quotient.
mg/kg =	Milligrams per kilogram.
NA =	Not available.
NOAEL HQ =	No observed adverse effect level hazard quotient.
[a]	Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b]	See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate. R5: Region 5 Ecological Screening Levels (USEPA 2003e; R5). EcoSSL: USEPA Ecological Soil Screening Levels (USEPA 2005b, EcoSSL). Where readily available (i.e., EcoSSLs), the basis of the ESL is presented.
[c]	Foodchain modeling was conducted for bioaccumulative COPECs.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.
