mg/kg	Milligrams per kilogram.
µg/L	Micrograms per liter.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

Miscellaneous											
Total Organic Carbon	- -	- -	- -	mg/kg	NA	NA	NA	21,842	39,276	NA	37,330 [35,146]

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

Table 9-9. Surface Water Analytical Results, Western Burning Ground, 1998 and 1999 ICF KE Remedial Investigation, Radford Army Ammunition Plant, Radford, Virginia.

µg/L	Micrograms per liter.
[a]	USEPA Regional Screening Levels (USEPA 2008a). Adjusted tap-water screening levels used to assess surface water at the NRU.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{max}	Concentration may exceed ceiling limit.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted tap water RSL.

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

Miscellaneous													
Total Organic Carbon	- -	- -	- -	mg/kg	53,700 K	NA	NA	28,600 K	24,200 K	NA	NA	NA	NA

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

µg/L	Micrograms per liter.
[a]	USEPA Regional Screening Levels (USEPA 2008a). Adjusted tap-water screening levels used to assess surface water at the NRU.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{max}	Concentration may exceed ceiling limit.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted tap water RSL.

Lead	400 {++}	800 {++}	26.8	mg/kg	**1,550**	**500**	**1,070**	**255 [212]**	NA	NA

mg/kg	Milligrams per kilogram.
[a]	USEPA Regional Screening Levels (USEPA 2008a).
[b]	Inorganics facility-wide background value taken from Facility-Wide Background Study Report, IT Corporation, 2001.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{++}	The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
{max}	Concentration may exceed ceiling limit.
{sat}	Screening level may exceed saturation concentration.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted soil RSL (Residential).
10.6 J	Highlighted value indicates constituent concentration is above adjusted soil RSL (Industrial).
16	Bolded inorganics constituent concentration indicates concentration is above facility-wide background value.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.

[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Zinc	7440-66-6	3.25E+03	3.10E+04	nm	2.30E+03	n		2.02E+02	no	**YES**	**YES**

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in surface soil (0-2 foot depth interval).
[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n SL < 100X c SL; ** = where n SL < 10X c SL; n = noncancer; m = concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.
[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).
[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in combined surface and subsurface soil.

[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Constituent of Potential Concern.
[b] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

[a] Background levels for inorganics are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.
[e] (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were inorganics present at concentrations below background (max • BKGD).
[f] Sum of individual dioxin/furan compounds multiplied by their individual TEFs.

Notes:
– = Not available or applicable.
mg/kg = Milligrams per kilogram.
NA = Not available or applicable.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The refined hazard quotient (HQ) is the ratio of the EPC to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.

Notes:

– = Not applicable.

COPEC = Constituent of Potential Ecological Concern.

EPC = Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration.
EPCs marked with "m" are the maximum concentration.

LOAEL HQ = Lowest observed adverse effect level hazard quotient.

mg/kg = Milligrams per kilogram.

NA = Not available.

NOAEL HQ = No observed adverse effect level hazard quotient.

[a] Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).

[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
R5: Region 5 Ecological Screening Levels (USEPA 2003e; R5).
EcoSSL: USEPA Ecological Soil Screening Levels (USEPA 2005b, EcoSSL).
Where readily available (i.e., EcoSSLs), the basis of the ESL is presented.

[c] Foodchain modeling was conducted for bioaccumulative COPECs.

µg/L	Micrograms per liter.
[a]	USEPA Regional Screening Levels (USEPA 2008a). Adjusted tap-water screening levels used to assess groundwater at the NRU.
{ca}	Carcinogen.
{nc}	Noncarcinogen.
*	Noncarcinogen screening level is less than one hundred times the carcinogen screening level.
**	Noncarcinogen screening level is less than ten times the carcinogen screening level.
{max}	Concentration may exceed ceiling limit.
B (Inorganics)	Constituent concentration quanitified as estimated.
B (Organics)	Constituent was detected in the associated method blank.
J	Constituent concentration quanitified as estimated.
K	Estimated concentration bias high.
L	Estimated concentration bias low.
NA	Not Analyzed.
[3.3]	Bracketed concentration indicates laboratory analytical result for duplicate sample.
24,400	Highlighted value indicates constituent concentration is above adjusted tap water RSL.

Notes:

J	Indicates an estimated value.
UJ	The compound was analyzed for but not detected. The associated value is the compound
1.83	Shading denotes that the detected concentration exceeded the screening level.

1. The tap water screening levels were obtained from the USEPA's RSL Table (December 2009)

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/L = Milligrams per liter.
ND = Non-detects.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.
[c] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
The UCLs were calculated using ProUCL 4.2. The UCL used is the one recommended by ProUCL 4.2.

Notes:
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/L = Milligrams per liter.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentrations in groundwater.
[b] The screening levels used were risk screening levels for tap water from USEPA (2008a). Screening levels based on non-cancer effects were adjusted by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit;
Some RSL values were based on surrogates as identified next to each value.
[c] Constituents detected with maximum concentrations greater than screening levels were considered COPCs unless they were known laboratory contaminants or essential nutrients.
[d] Chromium (III) (Insoluble Salts) was used for the tap-water RSL value.

Notes:
mg/L = Milligrams per liter.

[a] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
The UCLs were calculated using ProUCL 4.2. The UCL used is the one recommended by ProUCL 4.2.

1. Introduction

The purpose of this risk assessment is to evaluate current and reasonably anticipated future risks to human health and the environment associated with exposure to constituents detected in environmental media at the New River Unit (NRU) at the Radford Army Ammunition Plant (RFAAP).

ARCADIS prepared this human health and ecological risk assessment appendix to summarize the methodology and results of the risk assessments performed for the RFAAP-NRU. This appendix is divided into several sections and draws heavily on the information provided in the main body of the text. As such, it is not designed to be a stand alone document. Rather, it provides the general methodology used to evaluate potential exposures to receptors at the Study Areas identified at the RFAAP-NRU. The Study Areas are:

- Building Debris Disposal Trench (BDDT)
- Bag Loading Area (BLA)
- Igniter Assembly Area (IAA)
- Rail Yard (RY), and
- Western Burning Ground (WBG)

In addition to these five Study Areas, the risk assessment will evaluate potential exposure to facility-wide groundwater.

The purpose of the risk assessments was to evaluate the potential current and future excess lifetime cancer risks and potential hazards to both human and ecological receptors at the site from exposure to constituents detected in soil, groundwater, surface water, and sediment at the RFAAP-NRU. The risk assessments were conducted in a manner consistent with the approach outlined in the Master Work Plan (URS 2003) in compliance with Comprehensive Environmental Response, Compensation, and Liability Act/ Superfund Amendments and Reauthorization Act (CERCLA/SARA).

This human health and ecological risk assessment appendix is organized as follows:

- **Section 1 – Introduction.** This section provides background information related to the risk assessment.

- **Section 2 – Methods and Procedures.** This section provides the rational for the methods and procedures used during the evaluation of the data collected during the various phases of environmental investigation.

- **Sections 3 through 8 – Site Discussions.** These sections summarize the human health risk assessment (HHRA) and the ecological risk assessment (ERA) for each of the Study Areas and for facility-wide groundwater.

- **Section 9 – Conclusions and Recommendations.** This section presents a summary of the conclusions drawn from the HHRAs and ERAs.

- **Section 10 – References**.

2. Methods and Procedures

This section discusses the methods and procedures utilized to prepare the HHRA and ERAs at each of the five Study Areas (i.e., BDDT, IAA, BLA, WBG, and RY) and site-wide groundwater at the RFAAP-NRU.

2.1 Risk Assessment Data Sets

Samples collected during site investigations conducted from 1997 through 2008 were considered for inclusion in the risk assessment. The environmental data collected throughout the various phases of investigation were grouped by medium of interest (e.g., soil, sediment, groundwater and surface water) and then evaluated to produce risk assessment datasets.

2.1.1 Sample and Result Type

The following criteria were employed to determine whether a particular sample result is usable for risk assessment purposes:

- All soil sample types (i.e., hand auger, continuous core, direct-push technique) were considered usable for the risk assessment.

- Analytical results from soil samples collected from different depths at the same sampling location during the same sampling event were evaluated as independent samples.

- Data from field duplicate samples were generally considered usable for risk assessment. During statistical analysis of the data, data from a sample and its duplicate were treated as follows. In the case where an analyte was detected in either the sample or its duplicate, or in both, the higher concentration was conservatively used. Where the analyte was not detected, the lower detection method was used.

- Analytical results for the same constituent in one sample obtained by two or three different analytical methods (e.g., naphthalene, 2,4-dinitrotoluene) were generally considered usable for risk assessment. During statistical analysis of the data for constituents analyzed by two methods, the result of the more precise method was used (i.e., USEPA method 8260 over USEPA method 8270 for VOCs, USEPA method 8270-SIM over USEPA method 8270 for polycyclic aromatic hydrocarbons (PAHs), and USEPA method 8330 over USEPA method 8260 or USEPA method 8270 for explosives).

- Both filtered and unfiltered groundwater samples were collected at the RFAAP-NRU during the 2008 and 2010 sampling events, providing total and dissolved metals concentrations. Filtered groundwater data offers a better measure of the water quality as unfiltered data might have a high level of uncertainty associated with it as it could reflect constituents absorbed/adsorbed on particles in the water and not dissolved in the water itself. Filtered samples were available for those wells where the turbidity could not be reduced to an appropriate level. For these wells, the filtered samples were used rather than the unfiltered samples. If the turbidity was low, then a filtered sample was not collected. Because of the uncertainty in the turbidity levels in the groundwater samples collected in 2007, the total inorganics data from the 2007 sampling event were not used in the groundwater evaluation. However, the data for the organic constituents detected during the 2007 sampling event were included in the evaluation, along with the data from the 2008 and 2010 events.

- Fish tissue samples (fillet and whole body) were collected from the unnamed pond in the WBG. The fish filets data were used in the HHRA and the whole body data were used in the ERA.

2.1.2 Evaluation of Vertical and Spatial Data Distribution

Each of the five Study Areas was considered one exposure unit in the HHRA and the ERA. Therefore, soil, sediment and surface water data were spatially distributed into the five Study Areas: BDDT, IAA, BLA, WBG, and RY. However, groundwater was handled on a regional basis, rather than site-by-site. Groundwater is mobile and flows beneath the NRU and as such is therefore better handled on a site-wide basis.

Soil data were further subdivided by sample depth interval based on the exposure pathways identified at the site. In brief, data were categorized as follows:

- Surface soil, including soil samples collected from depths of 0 to 2 ft bgs, were used to evaluate current and potential future exposures to surface soils in the HHRA. These included samples collected from the 0-0.5, 0-1, 1-2 and 0-2 foot depth increments.

- For ecological receptors, surface soil is defined as soil from the ground surface to a depth of one foot below ground surface (bgs). Soil samples collected from depths greater than one foot bgs are not considered because wildlife typically inhabit only the uppermost portion of the soil column (USEPA 1993a,b) Thus, for the ecological risk assessment, only data from those samples collected from depths of 0 to 1 foot bgs were used to evaluate exposure.

- Surface and subsurface soil data were combined and used to evaluate the scenarios involving potential future exposure to subsurface soils in the HHRA.

2.1.3 Evaluation of Constituent Classes

Some constituents, especially those in the same class of compounds, behave similarly, thus they were grouped together for evaluation in the HHRA and/or the ERA, as discussed below.

The toxicity of dioxins and furans has been studied in relation to the toxicity of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Screening levels and toxicity values for human health effects are available for most of the individual dioxins and furans. However, ecological screening levels are only available for 2,3,7,8-TCDD. To evaluate exposure to other dioxin congeners in the ERA, their TCDD toxic equivalents (TEQ) were calculated using the 2005 World Health Organization (WHO) toxicity equivalency factors (TEFs) (WHO 2005) following USEPA guidance (USEPA 2003a).

2.1.4 Data Summaries

After the risk assessment datasets were prepared, the data included in each dataset were summarized, statistically analyzed, and then tabularized by highlighting: the number of detects, number of samples, frequency of detection (FOD), minimum and maximum detected concentrations, minimum and maximum detection limits, and the exposure point concentrations (EPCs) following applicable guidance (USEPA 1992; 1989).

The data summaries, including maximum concentrations and EPCs for soil, sediment, and surface water for the five Study Areas, whole body and fish fillet tissue data from the unmanned pond in the WBG, and for site-wide groundwater at the RFAAP-NRU are presented and discussed in the report sections devoted to those areas.

2.2 Human Health Risk Assessment Methods and Procedures

The purpose of the HHRA is to evaluate the potential current and future risks and potential hazards to human health associated with constituents detected in surface and subsurface soil, groundwater, sediment and surface water samples collected at the RFAAP-NRU. The HHRA approach is based on the Master Work Plan (URS 2003) in compliance with CERCLA/SARA and pursuant to RCRA Corrective Action requirements. Methods used in the HHRA were in compliance with USEPA guidance for risk assessments (USEPA 2005; 2004a; 2000a; 1997a; 1992; 1991a; 1989). The HHRA discussion is organized into the following components:

- **Constituent Characterization**: identifies the most prevalent and toxic constituents to be carried through the HHRA – the constituents of potential concern (COPCs). The physical and chemical properties of those constituents are also identified in this step.

- **Toxicity Assessment**: identifies and presents summaries of the general toxicological properties of the COPCs.

- **Exposure Assessment**: identifies the potential human exposure scenarios relevant to the risk assessment.

- **Risk Characterization**: presents the estimated human health risks associated with the identified COPCs and the relevant human exposure scenarios.

- **Uncertainty Analysis**: discusses the inherent uncertainties in the risk assessment process.

- **Summary and Conclusions**: summarizes the results of the HHRA.

2.2.1 Constituent Characterization

This section discusses the methods used to select COPCs for the HHRA and the physical and chemical properties of the selected COPCs.

2.2.1.1 Selection of Constituents of Potential Concern

Environmental data collected from each of the Study Areas are initially discussed by comparison to screening criteria. Comparison criteria are constituent and medium specific concentrations that are used to provide a reference value for site specific analytical data. Comparison criteria are typically published values that are based on calculations which assess the increase in risk under default assumptions to a given population based on the concentrations of constituents in environmental media at a site. These values can be used to assess the risk to a human population or to an ecological population.

COPCs were identified for each of the Study Areas by comparing maximum detected concentrations to human health based screening levels. If the maximum detected concentration was greater than the screening level, the constituent was identified as a COPC and quantitatively evaluated in the HHRA. Screening levels used for soil and sediment COPC selection were based on residential and industrial soil RSLs presented in the USEPA's RSL table (USEPA 2009a). Screening levels used for surface water COPC selection were based on the tap water RSLs (USEPA 2009a). Groundwater COPC selection also relied upon tap water RSLs (USEPA 2009a). Because substantial groundwater data have been collected at the Site, it was not necessary to complete a COPC screen using the soil RSLs that have been derived based on potential leaching to groundwater.

The Study Area assessments presented in this appendix utilize human health based screening levels derived from those presented in the United States Environmental Protection Agency's (USEPA's) Regional Screening Level (RSL) table (USEPA 2009a) as comparison criteria. Screening levels for soil and sediment were based on industrial and residential soil RSLs while screening levels for groundwater and surface water were based on tap water RSLs. The RSLs are calculated to demonstrate the concentration of a given constituent that will not result in an increase in risk to an individual beyond a hazard quotient (HQ) of 1 for non-carcinogenic compounds and an increase in cancer risk of 1×10^{-6} for potentially carcinogenic compounds. Because the Study Areas presented in this report are potentially contaminated with multiple constituents, and because noncarcinogenic effects can sometimes be cumulative, the RSLs based on noncarcinogenic effects were adjusted to reflect a target HQ of 0.1, where applicable (i.e., the published RSLs for non-carcinogens were divided by 10). For screening levels based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c** in RSL table), the non-cancer level was used after adjustment. Where appropriate, surrogate RSLs were used for constituents that lack screening levels. The adjusted RSLs are referred to as industrial and residential RSLs in this report. Table A.2-1 presents a summary of the RSLs utilized during the data comparison process.

It should be noted that there is no RSL available for asbestos. However, it is known that concrete slab floors in some buildings in the BLA and IAA Buildings were covered in a conductive flooring material that contained asbestos. Removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and break away from the underlying concrete. In some cases, the flooring has degraded into a red powder-like material and washed onto the surrounding soils. Since it is known that asbestos is present in some portions of the site, this was carried through as a COPC. However, asbestos is evaluated somewhat differently from other constituents. Thus the general approach used to evaluate it is provided in Section 2.2.4 with site-specific discussions included for both the BLA and IAA soils.

In addition to the RSLs, inorganic constituents detected in soil were compared to the background inorganics concentrations presented in the *Facility-Wide Background Study Report* (IT 2001). The background inorganics concentrations are based on calculated 95% UTLs generated from a facility-wide data set that incorporates both surface and subsurface soil from the RFAAP-MMA and the RFAAP-NRU. The calculated background concentrations are utilized to help differentiate between naturally occurring inorganic concentrations and concentrations resulting from human influence. Inorganics are not considered to be site related contaminants unless the concentrations are above the background concentrations. Table A.2-2 presents a summary of the background inorganics concentrations for the RFAAP. As indicated in this table, some of the background concentrations are greater than the soil RSLs.

Fish tissue data can be compared to fish consumption limits as set in USEPA's Guidance for Assessing Chemical Contamination Data for Use in Fish Advisories (USEPA 2000a). However, the guidance did not include any of the detected constituents in fish tissue. Therefore, all constituents detected were selected as fish tissue COPCs.

Constituents selected as COPCs based on human health protection were carried forward into the HHRA.

2.2.1.2 Physical and Chemical Properties

The environmental fate and transport of constituents depend on the physical and chemical properties of the constituents, the environmental transformation processes affecting them, and the media through which the constituents are migrating. The physical and chemical properties for the COPCs used in the risk assessment are summarized in Table A.2-3. This table includes the molecular weight, water solubility, vapor pressure, Henry's Law Constant, diffusivity in air and water, the organic carbon partition coefficient (K_{oc}), and the octanol-water partition coefficient (K_{ow}).

2.2.2 Toxicity Assessment

The toxicity assessment discusses the two general categories of toxic effects (non-carcinogenic and carcinogenic) and constituent-specific toxicity values used to calculate potential risks for these two types of toxic effects. Toxicity values for potential non-carcinogenic and carcinogenic effects are determined from available databases. For the HHRA, toxicity values were obtained from the following sources in order of priority as recommended by USEPA (2003b):

- USEPA Integrated Risk Information System (IRIS) database (USEPA 2009b)
- USEPA's National Center for Environmental Assessment Provisional Peer-Reviewed Toxicity Values as reported in USEPA RSL Tables (USEPA 2009a)
- USEPA's Health Effects Assessment Summary Tables (HEAST; USEPA, 1997b)

Other sources used included the California Environmental Protection Agency (Cal EPA), the Agency for Toxic Substances and Disease Registry (ATSDR) and the World Health Organization (WHO), as referenced by USEPA (2009a).

2.2.2.1 Toxicity Values for Non-carcinogenic Constituents

For many non-carcinogenic effects, protective mechanisms must be overcome before an effect is manifested. Therefore, a finite dose (threshold), below which adverse effects will not occur, exists for non-carcinogens. Depending on the dose, a single compound might elicit several adverse effects within a given exposure route or during the duration of exposure. The susceptibility of the individual may also influence the adverse effect caused by various constituents. Constituents may exhibit their toxic effects at the point of application or contact (local effect) or at other sites (systemic effects) after they have been distributed throughout the body. Most constituents can produce more than one type of toxic effect, depending on the dose and the susceptibility of the exposed individual or receptor. The goal of toxicity studies for application in risk assessment is to identify the most sensitive toxic effect and the exposure levels that are expected to be safe. The potential for non-carcinogenic effects is estimated by comparing a calculated exposure dose with a reference dose (RfD) for each individual constituent. The RfD represents a daily exposure level that is designed to be protective of human health, even for sensitive individuals or subpopulations.

For a given constituent, the dose or concentration that elicits no adverse effect when evaluating the most sensitive response in the most sensitive species is referred to as the “no observed adverse effect level” (NOAEL). The NOAEL is used to establish non-cancer toxicity values (called RfDs). The RfD represents a daily exposure level that is not expected to cause adverse non-carcinogenic health effects. Chronic RfDs are used to assess long-term exposures ranging from 7 years to a lifetime. Subchronic RfDs are used to evaluate the potential for adverse health effects associated with exposure to constituents over a period of 2 weeks to 7 years. HEAST was the primary source for subchronic RfDs. Where subchronic RfDs were not available from HEAST, chronic RfDs were used. Where the chronic to subchronic uncertainty factor had been reported, the subchronic to chronic uncertainty factor was removed from the chronic RfD and the subchronic RfD was used in the evaluation. If the subchronic to chronic uncertainty factor was not available, the chronic RfDs were used.

Table A.2-4 presents the RfDs used to assess oral and dermal exposure, and Table A.2-5 presents the RfDs used to assess inhalation exposure. Tables A.2-4 and A.2-5 also present the target sites associated with the non-carcinogenic toxicity values for each constituent varying with the exposure route. USEPA confidence values and uncertainty factors associated with the RfDs also are listed (USEPA 2009b). The uncertainty factor represents areas of uncertainty inherent in the extrapolation from the available data. The confidence levels (low, medium, high) assess the degree of confidence in the extrapolation of available data.

2.2.2.2 Toxicity Values for Carcinogenic Constituents

Cancer induction in humans and animals by constituents proceeds through a complex series of reactions and processes. Carcinogenic constituents may produce tumors at the point of application or contact, or they may produce tumors in other tissues after they have been distributed throughout the body. Some constituents are associated only with one or two tumor types while others may cause tumors at many different sites.

USEPA uses a cancer weight-of-evidence (WOE) descriptor to describe a substance’s potential to cause cancer in humans and the conditions under which the carcinogenic effects may be expressed. This judgment is independent of consideration of the agent’s carcinogenic potency. Under EPA’s 1986 guidelines for carcinogen risk assessment, the WOE was described by categories “A through E”—Group A for known human carcinogens through Group E for agents with evidence of noncarcinogenicity. Under the EPA’s 2005 guidelines for carcinogen risk assessment, a narrative approach, rather than categories, is used to characterize carcinogenicity. Five standard weight-of-evidence descriptors (*Carcinogenic to Humans, Likely to Be Carcinogenic to Humans, Suggestive Evidence of Carcinogenic Potential, Inadequate Information to Assess Carcinogenic Potential, and Not Likely to Be Carcinogenic to Humans*) are used as part of the narrative (USEPA 2005d).

For carcinogens, USEPA has historically used an extremely conservative approach in which it is assumed that any level of exposure could cause cancer. Based on this assumption, USEPA extrapolates from laboratory animal data using a mathematical model known as the linear multi-stage model. This model plots a line through the zero point and, based on the slope of this dose-response line, assigns a risk level for increasingly smaller doses of a particular compound. The 95 percent upper confidence limit for the slope of this line, called the cancer slope factor (CSF), is used to calculate the probability of an effect associated with a given dose. USEPA's slope factors thus are determined by a methodology that is likely to overestimate real risk.

Tables A.2-6 and A.2-7 present the carcinogenic toxicity values for oral and dermal exposure and inhalation exposure (respectively) for the COPCs at the site. The carcinogenic toxicity value used in the calculation of potential cancer risks is the CSF, which is derived from the conservative assumption that any dose level has a possibility of causing cancer. The cumulative dose, regardless of the particular exposure period, determines the risk; therefore, separate CSFs are not derived for subchronic and chronic exposure periods.

In accordance with USEPA (2005c) *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens* (Supplemental Guidance) PAHs, which have been identified as potentially acting using a mutagenic mode of action, were evaluated using age-dependent adjustment factors (ADAFs) for assessing carcinogenic risk associated with early-life exposures. Because site workers and hypothetical future construction workers are assumed to be adults (i.e., 18 years of age or older), these adjustments for early-life exposure were only necessary for the residential scenarios. USEPA guidance recommends the application of a default ADAF of 10 for exposure up to the age of 2 years, an ADAF of 3 for exposures during 2 to 16 years of age, and no adjustment for ages 16 and older. However, as stated in the Supplemental Guidance, "Default adjustment factors are meant to be used only when no chemical specific data are available to directly address cancer susceptibility from early-life exposure to a carcinogen acting through a mutagenic mode of action" (USEPA 2005c, p. vi). Consistent with this approach, chemical-specific ADAFs were calculated for PAHs using the methodology outlined in the Supplemental Guidance. Using the data on only benzo(a)pyrene from both 1 and 15 day old mice, USEPA determined that the average ratio of the potency factors of the animals exposed early in life to those exposed later in life was a factor of 4.6. This differs from the average default ratio of 10 because the default value is dominated by data on other chemicals. The chemical-specific ADAF for 2-16 year old receptors is derived in the same manner as that used in the Supplemental Guidance to derive the default value. The ADAF of 2.1 for the 2 to 16 year old is half the difference between 1 and 4.6 on a logarithmic scale. Based on this chemical-specific analysis, chemical-specific ADAFs of 4.6 were used for 0 to 2 years, 2.1 for 2 to 16 years of age, and no adjustment for ages 16 and older.

In this assessment, the residential scenario was evaluated in two parts: the first six years as a young child (0-6 years) and the remaining 24 years as an older child/adult (6-30 years). These two cancer risk calculations were then summed to derive a total cancer risk over the 30-year exposure period. For the mutagenic calculations, the specific ADAFs were incorporated appropriately into the child- and adult-specific calculations. Specifically, an ADAF of 4.6 was applied when assessing exposures during the first two years of life. An ADAF of 2.1 was applied for the remaining four years (ages 2 to 6 years) in the child scenario. For the adult residential scenario, an ADAF of 2.1 was used for 10 years of exposure to address exposures between the ages of 6 and 16, and no ADAF was applied for the remaining 14 years of exposure up to age 30 (USEPA 2005c).

2.2.2.3 Dermal Toxicity Values and Dermal Absorption

Whenever possible, route-specific toxicity values have been used; however, USEPA has not yet developed toxicity values for dermal exposures. For this reason, the oral toxicity values (RfD_o and CSF_o) and the oral absorption efficiency were used to derive adjusted toxicity values (RfD_a and CSF_a) (adjusted to the absorbed dose) for use in assessing dermal exposure (USEPA 1989):

$$RfD_a = RfD_o \times \text{Oral Absorption Efficiency}$$

$$CSF_a = CSF_o / \text{Oral Absorption Efficiency}$$

The adjusted toxicity values represent the theoretical toxicity of the orally absorbed dose of the constituent. The USEPA (2004a) guidance recommends that the oral toxicity values for organic constituents should not be adjusted to assess dermal exposure (i.e., oral absorption efficiency = 1). Table A.2-4 presents the oral absorption efficiency values and the RfD_as used to assess risk for the dermal exposure route. Table A.2-6 presents the CSF_as. Uncertainty is associated with the adjusted toxicity values and with the dermal risks derived using these values due to the uncertainty in the oral toxicity values combined with the uncertainty in the oral absorption efficiency default and constituent-specific values. However, the calculated dermal risks are expected to be very conservative and, therefore, will overestimate human health risks.

Table A.2-8 presents the dermal absorption efficiencies for COPCs identified at the RFAAP-NRU. The dermal absorption efficiency is used to estimate dermal uptake from a soil matrix.

2.2.2.4 Toxicity of Lead

The USEPA identifies lead as a "probable human carcinogen" based on sufficient animal evidence but inadequate human evidence (USEPA 2007b). However, the USEPA does not recommend evaluating lead cancer risk using a CSF (USEPA 2003c). Instead, lead non-carcinogenic risks (identified as neurological effects) are evaluated by predicting blood-lead concentrations using toxicokinetic modeling. This is because there is a strong correlation between lead exposure and resulting blood lead levels.

2.2.3 Exposure Assessment

Exposure pathways were identified based on the site characterization information and the fate and transport properties of the COPCs to identify likely points where human receptors may come in contact with affected media under current or potential future conditions at the site. The principal pathways by which exposure could occur were identified for human receptors.

An exposure pathway is defined by the following four elements:

(1) a source and mechanism of constituent release to the environment;

(2) an environmental transport medium for the released constituent;

(3) a point of potential contact with the contaminated medium (the exposure point); and

(4) an exposure route at the exposure point.

The purpose of the exposure assessment is to estimate the way(s) a population may potentially be exposed to constituents at a site. This typically involves projecting concentrations along potential pathways between sources and receptors. The projection usually is accomplished using site-specific data and, when necessary, mathematical modeling. Exposure can occur only when the potential exists for a receptor to contact released constituents directly or when there is a mechanism for released constituents to be transported to a receptor. Without exposure there is no risk; therefore, the exposure assessment is a critical component of the risk assessment.

2.2.3.1 Conceptual Site Model

The conceptual site model (CSM) provides the risk assessment framework. It characterizes the primary and secondary potential sources and release mechanisms and identifies the primary exposure points, receptors, and exposure routes. Exposure points are places or "points" where exposure could potentially occur, and exposure routes include the basic pathways through which COPCs may potentially be taken up by the receptor. The potential exposure pathways for the RFAAP-NRU are presented in Figure 2-1.

The potentially exposed receptors at the site have been identified based on both current and reasonably anticipated future land use of the areas located in the vicinity of the site. As discussed in Section 1.1, the site is currently utilized as a storage facility for operations at the RFAAP-MMA. There are no active manufacturing operations taking place and there are no residents at the site. RFAAP-NRU is not currently used. There are buildings and facilities that remain from previous operations at this unit. There are areas of undeveloped area as well. While the surrounding land use is rural, the industrialized nature of RFAAP is unlikely to change in the future. Depth to groundwater ranges from 13 feet bgs to more than 150 feet bgs. Groundwater in the vicinity of the site is not being used as a potable water source; however, as a conservative measure, consumption of groundwater as a drinking source and dermal exposure due to employee handwashing were evaluated for a site commercial/industrial worker.

The only potential current receptors are site workers who are involved in maintenance and mowing activities. It is possible, however, that the site may be redeveloped in the future for commercial purposes. For this reason, the exposure scenarios for site workers assume an annual occupational exposure frequency of 250 days/year, even though the exposure frequency for current site workers is less frequent. All of these current and future site workers could have potential exposure to surface soils.

Due to the industrialized/military nature of the site, redevelopment of the site for residential purposes is highly unlikely. Remedial decisions will be based on the current and reasonably expected future use (military industrial). However, hypothetical exposure of residential receptors was evaluated in the risk assessment as a conservative measure and to assist the Army in making risk management decisions.

Exposure scenarios in the future could potentially include exposure to surface and subsurface soil, sediment, surface water, and groundwater used as a potable water source. Exposure to soil for the residential receptor could occur through ingestion, dermal contact, and inhalation of vapors and/or COPCs adhered to fugitive dust. Exposure to sediment for the resident receptor could occur through ingestion and dermal contact during wading. Exposure to surface water could occur through ingestion or dermal contact during wading while exposure to groundwater could occur though all routes if groundwater is used as a domestic water supply. Further, resident receptors may also be exposed to constituents that might have accumulated in fish tissue samples collected from the unnamed pond in the WBG.

In the event of site redevelopment, construction workers may, in the future, be exposed to surface and subsurface soil if excavation activities take place.

Exposures of hypothetical current or future trespassers were not evaluated because their exposures, if any, would be of a limited frequency and duration since the site is completely fenced and access is controlled. This hypothetical receptor would have far less exposure than the receptors selected for quantitative evaluation (e.g., an exposure duration of five days per year for a trespasser versus 250 days per year for the industrial site worker or 350 days per year for a residential scenario).

Likewise, exposure of hypothetical current or future angler receptors from ingestion of fish from the unnamed pond at the WBG was not evaluated because the exposure, if any, would be of a limited frequency and duration since the site is completely fenced and access is controlled. In addition, a hypothetical angler receptor would have far less exposure than the resident angler selected for quantitative evaluation.

In addition, the potential for exposure to vapors migrating to indoor air from combined surface and subsurface soil and from groundwater was evaluated for future site workers as well as hypothetical future adult and child residents using the screening-Level Johnson and Ettinger Model (USEPA 2004b). The USEPA (2004b) screening models estimate the potential associated risk and calculate risk-based concentrations for residential and industrial settings. The individual concentration sheets produced during the model runs are presented, along with the exposure parameters and site-specific soil information available for the site.

2.2.3.2 Exposure Point Concentrations

EPCs were calculated for each constituent at each Study Area. The EPC is a representative constituent concentration that a receptor may contact at an exposure point over the exposure period (USEPA 1989). According to USEPA risk assessment guidance (2007a; 2002a,b; 2000a; 1992), the EPC is an estimate of the arithmetic average concentration for a constituent. Ideally, the EPC should be the true average concentration; however, because of the uncertainty associated with estimating the true average concentration based on a limited dataset, the estimated upper confidence level (UCL) on the mean (i.e., a UCL of 95 percent or higher) should be used as the EPC.

Calculation of UCLs was performed using the USEPA's ProUCL (Version 4.0; USEPA 2007a). UCLs recommended by the software were used. UCLs were calculated where there were a minimum of eight samples in the dataset and the constituent was detected in a minimum of five samples. The maximum concentration was used as the EPC where the UCL could not be calculated. For the human health risk assessment, ingestion of fish caught from the pond in the WBG was based on the maximum concentration of the fish fillet data. This is a highly conservative assumption and is discussed in the uncertainty section (Sections 2.3.5 and 2.4.3.6). Following USEPA (2007a) guidance, exposure to lead was evaluated using arithmetic average concentrations rather than UCLs.

Soil, sediment, surface water, and groundwater EPCs are presented within the data summary tables in the report sections devoted to the Study Areas.

EPCs in air for non-volatiles that would adhere to dust were estimated using a dust Particulate Emission Factors (PEF). EPCs for volatile COPCs were estimated using volatilization factors (VFs) where applicable. Those factors are presented in Table A.2-9.

2.2.3.3 Exposure Assumptions

The receptors and the receptor-specific exposure parameters are summarized in Table A.2-10, and are discussed below.

2.2.3.3.1 Site Worker

Site workers are potential receptors at the RFAAP-NRU. They may occasionally be exposed to site-related constituents through contact with surface soil. They may also contact surface water and sediment while cutting the grass on the stream banks. This possibility was assessed via a wading scenario. The exposure assumptions for this receptor are included in Table A.2-10 and are summarized as follows:

- Adult body weight of 70 kilograms (kg) (USEPA 1991a; 1989)

- Exposure duration 25 years (USEPA 1991a; 1989)
- Exposure frequency of 250 days/year (USEPA 1991a; 1989)
- Exposure frequency – wading scenario 26 days/year (professional judgment assuming activity occurs one day per week for six months of the year)
- Groundwater exposure time of 0.17 hour/day, assuming workers wash their hands 5 times a day, for 2 minutes each time (USEPA 1997a)
- Soil exposure air-inhalation rate of 20 cubic meters per day (m^3/day) (USEPA 1991a; 1989)
- Surface water exposure air-inhalation rate of 2 m^3/day (USEPA 1997a)
- Soil incidental ingestion rate of 100 milligrams per day (mg/day; USEPA 2002a)
- Sediment incidental ingestion rate of 50 milligrams per day (mg/day; USEPA 1991a)
- Groundwater ingestion rate of 2 L/day (USEPA 1991a; 1989)
- Surface water ingestion rate of 0.05 liters per hour (L/hour) (USEPA 1989)
- Soil exposed skin surface area of 3,300 square centimeters (cm^2), which is the sum of the mean values for hands, forearms, and face for an adult (USEPA 2004a)
- Groundwater skin surface area exposure of 2,400 cm^2 , averaging surface are of the face, hands, and forearms (USEPA 2004a)
- Sediment and surface water exposed skin surface area exposure of 5,000 cm^2, averaging surface area of feet, lower legs, hands, and forearms (USEPA 1997a)
- Soil to skin adherence rate of 0.2 milligrams per square centimeter per day (mg/cm^2/day; USEPA 2004a)
- Sediment to skin adherence rate of 0.6 mg/cm^2/day (USEPA 2004a)
- Surface water exposure time of 1 hour/day (USEPA 1997a)

2.2.3.3.2 Hypothetical Future Residents

Residential development of the RFAAP-NRU is not expected to occur and the current land use associated with the site is not expected to change. As a result, future use of the site for residential purposes is considered unlikely, but will be considered here to assist the Army in making risk management decisions. Residential scenarios include exposure to site-related constituents through contact with surface and subsurface soil, sediment, surface water and with groundwater if it is used as a potable water source. The exposure assumptions for the hypothetical future residents are presented in Table A.2-10 and are summarized below.

- Adult body weight of 70 kg and a young child body weight of 15 kg (USEPA 1991a; 1989)
- Exposure duration of 24 years for an adult and 6 years for a child (USEPA 1989; 1991a)
- Soil and groundwater exposure frequency of 350 days/year (USEPA 1991a; 1989)
- Wading exposure frequency of 48 days/year (professional judgment assuming twice per week during the six warm months of the year) and that there would be rain four of those days and exposure would not occur
- Wading exposure time of 1 hour/day (USEPA 1997a)
- Soil and groundwater exposure air-inhalation rates of 20 m^3/day for an adult (USEPA 1991; 1997a), and 10 m^3/day for a child (USEPA 1997a)
- Surface water exposure air-inhalation rate of 2 m^3/day (USEPA 1997a)
- Soil incidental ingestion rate of 100 mg/kg for adults and 200 mg/kg for young children (USEPA 1991a)
- Groundwater ingestion rate of 2 L/day for adults and 1 L/day for young children (USEPA 1991a; 1989)
- Surface water incidental ingestion rate of 0.05 liters per hour (L/hour) (USEPA 1989)
- Soil adherence rate of 0.07 mg/cm²/day for adults and 0.2 mg/cm²/day for young children (USEPA 2004a)
- Sediment to skin adherence rate of 0.6 mg/cm^2/day for adults and 0.2 mg/cm^2/day for young children, based on exposure to wet soil (USEPA 2004a)
- Soil skin surface area exposure of 5,700 cm^2 for adults and 2,800 cm^2 for young children, which are the sum of the 50th percentile values for the face, feet, lower legs, hands, and forearms (USEPA 2004a)
- Groundwater skin surface area (whole body) exposure of 18,000 cm^2 for adults and 6,600 cm^2 for young children (USEPA 2004a)

- Sediment and surface water skin surface area exposure of 5,000 cm^2 for adults and 1,900 cm^2 for young children, which are the sum of the 50th percentile values for feet, lower legs, hands, and forearms (USEPA 1997a)
- Ingestion rate of fish of 0.054 kg/day for both child and adult (USEPA 1997a)

2.2.3.3.3 Hypothetical Future Construction Worker

Construction workers may be present at the RFAAP-NRU in the future to work on new construction or excavation activities; therefore, this exposure scenario was evaluated based on a hypothetical construction project. The construction project was assumed to take 6 months (130 working days) to complete. Construction workers are not likely to come into contact with shallow groundwater during a hypothetical construction project. This assumption is based upon the consideration that, typical foundation construction work would not require soil contact below 10 feet, whereas the depth to shallow groundwater is at least 10 feet. In fact, the depth to groundwater for a majority of the sites at the NRU is far greater than 10 ft; in particular, the depth to groundwater at the BLA, IAA, and NBG site are 120 ft, 30 ft, and 90 ft; respectively. Furthermore, the possibility of trenching equipment/operators being exposed to groundwater is minimized because the groundwater is located within the karst bedrock underlying the site, and standard trenching equipment/techniques are not suitable for working within the karst bedrock. .

The exposure assumptions for this potential receptor are included in Table A.2-10 and are summarized as follows:

- Adult body weight of 70 kg (USEPA 1991a; 1989)
- Exposure duration 1 year (professional judgment)
- Exposure frequency of 130 days/year (professional judgment assuming 5 workdays/week for 6 months)
- Inhalation rate of 20 m^3/day (USEPA 1991a; 1989)
- Incidental soil ingestion rate of 330 mg/day (USEPA 2002a)
- Soil to skin adherence factor of 0.3 mg/cm^2/day (USEPA 2002a)
- Exposed skin surface area of 3,300 cm^2, which is the sum of the 50th percentile values for hands, forearms, and face for an adult (USEPA 1997a)

2.2.4 Risk Characterization

The equations used in the risk characterization calculations for exposure to soil, surface water, and sediment are presented in Tables A.2-11 through A.2-13. Equations for exposure to fish ingestion are presented in Table A.2-14, and equations for exposure to groundwater used as a domestic water supply are presented in Table A.2-15.

Potential risks to human health are evaluated quantitatively by combining calculated exposure levels and toxicity data. A distinction is made between non-carcinogenic and carcinogenic endpoints as discussed in the subsections below.

2.2.4.1 Non-carcinogenic Effects – Hazard Quotients and Hazard Indices

Exposure doses are averaged over the expected exposure period to evaluate non-carcinogenic effects. The hazard quotient (HQ) is the ratio of the estimated exposure dose and the RfD. An HQ greater than 1 indicates that the estimated exposure level for that constituent is greater than the RfD. This ratio does not provide the probability of an adverse effect. Although an HQ of 1 indicates that health effects should not occur, an HQ that is greater than 1 does not imply that health effects will occur, but that health effects are possible.

The sum of the HQs is the hazard index (HI). A limitation with the HI approach is the assumption of dose additivity is applied to compounds that may induce different effects by different mechanisms of action. Consequently, the summing of HQs for a number of compounds that are not expected to induce the same type of effects or that do not act by the same mechanism may overestimate the potential for toxic effects (USEPA 1989). Consistent with USEPA risk assessment guidelines for constituent mixtures, in the event that the total HI for an exposure scenario is greater than 1, it is incumbent on a risk assessor to segregate HQs by target organ/critical effect (USEPA 1989). Therefore, if the calculated HI is greater than 1 as a consequence of summing several HQs for constituents not expected to induce the same type of effects or that do not act by the same mechanism, the HIs may be segregated by effect and mechanism of action to derive separate HIs for each target-organ/critical-effect group (USEPA 1989). The conclusions of the risk assessment are used to identify constituents of concern (COCs) that are used to focus remedial efforts at a site. COCs are those constituents with an HI greater than 1.

2.2.4.2 Carcinogenic Effects - Excess Lifetime Cancer Risk

The excess lifetime cancer risk (ELCR) is an estimate of the potential increased risk of cancer that results from lifetime exposure, at specified average daily dosages, to constituents detected in media at a site. Estimated doses or intakes for each constituent are averaged over the hypothesized lifetime of 70 years. It is assumed that a large dose received over a short period is equivalent to a smaller dose received over a longer period, as long as the total doses are equal. The ELCR is calculated as the product of the exposure dose and the CSF. The risk estimate is considered to be an upper-bound estimate; therefore, it is likely that the true risk is far less than that predicted by the model.

The USEPA considers ELCRs within the target risk range of 10^{-6} to 10^{-4} to be generally acceptable. USEPA (1991b) generally considers remediation of sites with risks less than 1×10^{-4} not to be warranted. The conclusions of the risk assessment are used to identify COCs that are used to focus remedial efforts at a site. COCs are those constituents with ELCRs greater than 1×10^{-4}.

2.2.4.3 Evaluation of Lead Exposures

Exposure to lead is evaluated differently than the other constituents. Cancer risk and non-cancer hazard quotients are not estimated from exposure to lead because health effects from exposure to lead are better characterized by estimating the amount of lead that may reach the bloodstream following exposure.

Consistent with current USEPA guidance (USEPA 2003c), USEPA's Adult Lead Methodology (ALM) model (USEPA 2003d) and USEPA's Integrated Exposure Uptake Biokinetic Model for Lead in Children (IEUBK; USEPA, 2005a) were used to evaluate the potential for adverse health effects from exposure to lead by adults and children, respectively. The models were used to calculate upper percentile blood-lead concentrations for each receptor, which were compared to the target blood-lead concentration of 10 micrograms per deciliter (µg/dL). While the ALM was designed to evaluate exposure to lead by workers, it was also used in this risk assessment to evaluate exposure to lead by adult residents.

The ALM calculates 95th percentile blood-lead concentrations by applying a geometric standard deviation to a central tendency estimate calculated from the user specified input parameters. Because the soil ingestion rates used to evaluate exposure to soil constituents other than lead are upper bound estimates, different soil ingestion rates are needed to evaluate exposure using the ALM. The USEPA (1997a) recommends 50 mg/day as a central tendency estimate of soil ingestion by adults. This value was used to evaluate exposure to lead by the commercial/industrial worker and the adult resident receptors. USEPA (2003c) recommends 100 mg/day as a central tendency estimate of soil ingestion rate for construction workers. This value represents the central tendency ingestion rate for soil contact intensive activities (including soil derived indoor dust) (USEPA 1997a; 2003c). This value is a conservative parameter to use for assessing daily exposure for the construction worker as heavy construction will most likely not occur continuously at the site during the entire construction period.

Default input parameters were used to evaluate the commercial/ industrial worker receptor using the ALM. The default intake rate is 50 mg/kg and the default exposure frequency is 219 days/year for a commercial scenario.

To evaluate an adult construction worker receptor by the ALM, the exposure frequency was set equal to 130 days/year and the intake rate was set at 100 mg/kg.

To evaluate an adult resident by the ALM, the exposure frequency was set equal to 350 days/year for exposure to soil and 48 days/year for exposure to sediment. Because of the intermittent nature of exposure of the adult resident to lead in sediment, a time-weighted average lead concentration was used at the Western Burning Ground to evaluate exposure to lead in soil and sediments together. This is the only area at the site where lead was identified as a COPC in both soil and sediments.

Default input parameters were used to evaluate exposure to soil for the child resident using the IEUBK. The IEUBK was used to assess potential for adverse health effects from lead in soil to children. At the Western Burning Ground, exposure to lead was evaluated using the time weighted average lead concentration in soil and sediments. However, because the sediments would not routinely produce dust in the home, but soil would, the indoor dust concentration was set at 70 mg/kg which was equal to the average soil concentration multiplied by the IEUBK default dust percentage (45 percent) as specified in the model.

Blood lead levels were estimated for the three areas where lead was a COPC: the IAA, the BLA, and the WBG. The model runs and the result summaries for each Study Area are discussed in the section of the report devoted to those Study Areas.

2.2.4.4 Evaluation of Asbestos Exposure

USEPA has recently developed a recommended framework for evaluating potential risks associated with asbestos in soil. This framework addresses the fact that asbestos concentrations in soil are not always good predictors of the level of exposure and risk that may be experienced by individuals who come into contact with that soil. This is because the potential risk experienced by those individuals is not a function of the concentration in the soil but is instead a function of their potential inhalation of asbestos fibers that may become airborne when and if soil is disturbed.

In recognition of this framework, a different approach was used to evaluate potential risks associated with asbestos in surface soil. This approach involved the calculation of air action levels (AALs) by combining the methodology outlined in USEPA's framework document with some of the scenario-specific exposure parameters discussed above. The AALs were then compared with airborne asbestos concentrations measured during activity-based air sampling, to determine whether asbestos might pose a potential risk to individuals who come into contact with that soil. The specific methodology for calculating the AALs is provided in Section 4.4.5.

2.2.5 Uncertainties in the Human Health Risk Assessment

The risk estimate presented here is a conservative estimate of potential risks associated with exposure to constituents detected in soil, groundwater, sediment, and surface water at the RFAAP-NRU. Uncertainty is inherent in the risk assessment process, and a discussion of these uncertainties is presented in this section. Each of the three basic building blocks for risk assessment (monitoring data, exposure scenarios, and toxicity values) contributes uncertainties. Each of the uncertainties is accounted for by using conservative assumptions wherever specific data are unavailable.

This risk assessment is based on the assumption that the available monitoring data adequately describe the occurrence of constituents in media at the site. Environmental sampling itself introduces uncertainty. This source of uncertainty can be reduced through a well-designed sampling plan, use of appropriate sampling techniques, and implementation of laboratory data validation and quality assurance and quality control (QA/QC). The data utilized in this report meet QA/QC requirements and are appropriate for use in a risk assessment.

The assumption that the concentrations will remain constant throughout the exposure period is a conservative approach, because ongoing natural attenuation and degradation processes likely will reduce the concentrations over time. Using the UCL or the maximum concentration as the EPC is also conservative. It is highly unlikely that receptors would be exposed to those upper bound concentrations over an extended period of time.

The toxicity values and other toxicological information used in this report likewise are associated with significant uncertainty. Many toxicity values are developed using results of studies in which laboratory animals are exposed to massively high doses of particular constituents in a controlled environment. As such, these studies do not represent realistic examples of lower level and variable human environmental exposures. In addition, many of the strains of laboratory animals used in toxicological studies are genetically homogeneous and are specifically selected because of their known sensitivities for certain endpoints (e.g., tumor formation) and thus are not representative of the more genetically diverse and heterogeneous human population. In addition, the effects shown by the animals in the high-dose studies often differ from effects reported for humans in parallel epidemiological studies. This is because a particular compound may have a different mechanism of action in laboratory animals than it does in humans. Even epidemiological studies, which are generally preferable to animal toxicity studies, are characterized by several uncertainties, such as differential exposures, confounding factors, and unknown (and uncontrolled) doses. Furthermore, some toxicity values are based on draft toxicity values and therefore may also produce uncertainty within the results.

PAHs were evaluated using a mutagenic adjustment for early life stage exposures. Much of the data used to calculate the ADAFs are based on tumor response rates in newborn and neonatal mice given very large bolus doses (75 – 150 ug/kg body weight) injected into their intraperitoneal cavities. Because this administration method has little relevance to human health risk assessment or exposure, it is likely that any mutagenic adjustment will overestimate potential risks.

Toxicity values are not available for dermal exposure. The USEPA-recommended approach to derivation of dermal toxicity values based on available oral toxicity values and oral absorption efficiencies contributes considerable uncertainty to the risk assessment.

Toxicity values were not available for d-limonene and 3-octanone. However, both of these compounds are naturally occurring and are also used in a variety of consumer products. For example, d-limonene is used as a flavoring agent and both are used in fragrances. Therefore, while toxicity values are not available for these two constituents, it is unlikely that their presence will significantly alter the conclusions of the risk assessment.

Uncertainty is also associated with constituent mixtures. Information on the toxicity of specific mixtures is rarely available. The procedure generally applied to a potential event of simultaneous exposure to multiple constituents from a variety of sources assumes dose additivity, although it is possible that the interaction of multiple constituents could be synergistic or antagonistic.

Potential exposure scenarios contribute uncertainty to the risk assessment as well. Exposure scenarios were developed based on site-specific information, USEPA exposure guidance documents, and conservative professional judgment. The hypothetical future residential scenarios which assumes that receptors will be exposed to site soil and also to groundwater that will be used as a potable water supply is highly unrealistic because the site will most likely never be used for residential use. Although uncertainty is inherent in the exposure assessment, and the exposure assumptions also were chosen to err on the side of conservatism, this uncertainty could lead to an overestimation or underestimation of potential risk.

2.3 Ecological Risk Assessment Methods and Procedures

Site-specific ERAs were conducted at each of the five Study Areas evaluated in this RI. The purpose of the ERAs was to evaluate the potential current and future risks and potential hazards to ecological receptors associated with constituents detected in surface soil, sediment, and surface water conditions at each of the Study Areas within RFAAP-NRU.

The ERAs were conducted in a manner consistent with USEPA guidance for ecological risk assessment (USEPA 2001a; 2000b; 1997c) and follow the approach in the Master Work Plan (URS 2003). The ERAs are intended to provide a conservative understanding of environmental conditions as they relate to the protection of wildlife populations and communities for risk management decision-making at the RFAAP-NRU

In accordance with USEPA guidance, the ERAs conducted for the five Study Areas at the RFAAP-NRU are comprised of a SLERA and a baseline ERA (BERA) (USEPA 2000b; 1997c). The SLERA evaluates the potential risk to terrestrial and aquatic ecological receptors exposed to detected constituents in surface soil, sediment, and surface water. The SLERA provides a conservative estimate of potential ecological risks and compensates for uncertainty by incorporating numerous conservative assumptions. The purpose of the SLERA is to determine whether or not there is a high probability that there are no ecologically significant risks that would merit additional evaluated as provided by a BERA (USEPA 2000b; 1997c). If the results of the SLERA warrant a BERA, the information developed in the SLERA is used to help focus the BERA. The BERA is more complex than the SLERA and uses more realistic and site-specific information about potential exposures and effects in order to evaluate potential ecological risks. Both a SLERA and a BERA were conducted for each of the five Study Areas at the RFAAP-NRU.

The approach used to assess ecological risks associated with the RFAAP-NRU is based on the USEPA eight-step process (USEPA 2001a; 2000b; 1997c), as summarized in Figure 2-2. An expanded view of the USEPA eight-step process is provided in Figure 2-3. As illustrated on Figure 2-3, the USEPA paradigm divides Step 3 into two pieces, Step 3a and Step 3b (USEPA 2000b). Step 3a allows for a more refined analysis of available information, while Steps 3b and beyond focus on further evaluation(s) for only those receptors, media, and constituents that are identified in previous steps. According to the USEPA (2000b), “for the majority of sites, ERA activities will cease after the completion of Step 3a.” The details of each step and how they relate to the site ERA are described in this section.

The ERA process culminates in clearly defined scientific management decision points (SMDPs). The SMDPs represent critical steps where risk management decision-making occurs. Generally, the following types of decisions are considered at the SMDPs.

- Whether the available information is adequate to conclude that ecological risks (if any) are negligible and, therefore, there is no need for further action on the basis of ecological risk.

- Whether the available information is inadequate to make a decision at this point and the ecological risk assessment process should continue.

- Whether the available information indicates a potential for adverse ecological effects and a more thorough assessment or remediation is warranted.

The remainder of this Section presents the methods used in the ERA and is organized as follows:

- Screening Level Ecological Risk Assessment – this section discusses the steps taken in the SLERA and indentifies elements that would indicate the need for a more refined BERA.

- Baseline Ecological Risk Assessment– this section discusses the steps taken in the BERA.

2.3.1 Screening Level Ecological Risk Assessment

A SLERA conservatively estimates potential risks that may affect ecological receptors, including terrestrial and aquatic organisms. The SLERA typically compensates for uncertainty in a precautionary manner, by incorporating numerous conservative assumptions. The outcome of the SLERA is the conclusion that either there is a high probability that ecologically significant risks are not posed to receptors, or further investigation in the form of a BERA is warranted. Consistent with USEPA (1997c) guidance, the SLERA is comprised of the following steps:

- Step 1: Screening-Level Problem Formation
- Step 1: Screening Level Ecological Effects Evaluation
- Step 2: Screening Level Exposure Estimate and Risk Calculation
- Scientific Management Decision Point (SMDP)

For each of the five Study Areas, a modified SLERA was conducted following the typical steps in a SLERA and also incorporating some steps typically taken later in the BERA, as a BERA was anticipated in each Study Area. Methods used during those steps of the SLERA are described below.

2.3.1.1 Step 1: Screening-Level Problem Formulation

Step 1 of a SLERA consists of both a screening level problem formulation and a screening level ecological effects evaluation. The screening-level problem formulation presents background information on site characterization, receptors, ecosystem characteristics, as well as information on the sources and effects of the stressors (USEPA 1998). This information is used to develop a CSM that illustrates the potential relationships between stressors, pathways, and receptors. The screening-level problem formulation provides information used to establish the overall goals, breadth, and focus of an ERA (USEPA 1998; 1997c).

The remainder of this section discusses the following components of the screening-level problem formulation for the RFAAP-NRU:

- Environmental Setting
- Identification of Constituents Detected
- Description of Constituent Fate and Transport Pathways

- Description of Constituent Mechanisms of Ecotoxicity
- Description of Potentially Exposed Receptors
- Identification of Potentially Complete Exposure Pathways
- Selection of Generic Assessment and Measurement Endpoints

2.3.1.1.1 Environmental Setting

This section describes the general habitat types present at and in the immediate vicinity of the site. As mentioned in Section 1, RFAAP-NRU is located in the mountains of southwestern Virginia and is comprised of two distinct areas: the MMA and the NRU. The NRU itself is also comprised of several Study Areas and this ERA is focused on the following five areas within the NRU: the BDDT, the IAA, the BLA, the WBG, and the RY. Terrestrial habitat and aquatic habitat is present at each of these areas. The terrestrial habitat consists of mixed forest, open fields, and grassy areas. The aquatic habitat consists of various storm water drainage channels, the unnamed creek in all areas of the NRU and Wiggins Spring and an unnamed pond in the WBG. A brief description of the environmental setting at each Study Area is presented in the report section devoted to that Study Area.

2.3.1.1.2 Identification of Constituents Detected

Ecological receptors at the site could potentially have direct contact with surface soil, sediment, and surface water. For the purposes of the ERA, surface soil is defined as soil from the ground surface to a depth of 1 foot bgs. Soil samples collected from depths greater than 1 foot bgs are generally not considered in ERAs because wildlife typically inhabit only the uppermost portion of the soil column (USEPA 1993a,b).

Soil data from ground-surface to a depth of 1 foot bgs, surface water data, and sediment data for five of the Study Areas in the RFAAP-NRU were evaluated as discussed in Section 2.1 and data summaries were prepared for each medium. The data summary tables present the frequency of detection, the range of sample quantitation limits, the range of detected concentrations, and the EPC for each detected constituent in each medium.

2.3.1.1.3 Description of Constituent Fate and Transport Pathways

Knowledge about the potential constituent fate and transport pathways is vital to understanding which constituents and receptors are associated with potentially complete current and future exposure pathways. This is because a constituent may reach an ecological receptor in a variety of ways. In addition, the pathway and route of exposure may have a strong influence on the ecological effect of a constituent. This information is used in the development of a CSM for potential ecological receptors. Constituent fate and transport pathways for the site are illustrated on Figure 2-4**.**

Terrestrial receptors can potentially be exposed to constituents in soil via direct contact. Further, constituents associated with soil may be carried via overland run-off to aquatic habitat. Likewise, aquatic receptors can potentially be exposed to constituents in sediment and surface water via direct contact.

2.3.1.1.4 Description of Constituent Mechanisms of Ecotoxicity

The mechanisms of ecotoxicity for constituents vary depending on a wide range of factors, such as constituent concentrations, the receptor species exposed, the exposure route (e.g., ingestion or direct contact), and physical factors (e.g., pH, temperature, oxygen levels, water hardness). Some of the effects that could be observed in wildlife are mortality, reduced reproductive ability, decreased fertility, decreased offspring survival, alteration of immune and behavioral function, decreased hatching success of eggs/larvae, and retarded growth (Sample et al. 1996; USEPA 2001b). The remainder of this subsection discusses mechanisms of ecotoxicity for the classes of constituents detected at the site. These descriptions of constituent mechanisms of toxicity are presented without consideration of constituent concentrations, as the descriptions are intended to convey an understanding of possible effects, rather than to describe the concentrations at which these effects might occur.

Volatile Organic Compounds

VOCs tend to attenuate rapidly in surface soil, sediment and surface water due to their inherent volatility. Although the effects of VOCs on ecological receptors are not well-understood, there have been extensive inhalation studies of the effects of VOCs under laboratory conditions. Inhaled volatile organics are typically metabolized in the body (often the liver), which may cause liver damage (depending on the organism) or the release of more toxic secondary metabolites. The VOCs or their metabolites may also cause neurological damage, and many are mutagenic or carcinogenic. Additionally, some VOCs are fetotoxic and/or teratogenic (USEPA 2009b; Sample et al. 1996).

Semi-Volatile Organic Compounds

SVOCs include a wide variety of compound classes, such as phenols, organochlorine alkenes, phthalates, and PAHs. SVOCs vary greatly in regard to their toxicity, mechanism of action, bioaccumulative potential, and susceptibility to being metabolized. Phthalates, a class of SVOCs, are known endocrine disruptors affecting sexual development in males. They are common in the environment, but do not dissolve in water easily and generally attach strongly to soil particles. They are primarily found in plastics used in soft toys, flooring, cosmetics, air fresheners and medical products (ATSDR 2008). PAHs such as acenaphthene and naphthalene, are often released to the environment as a result of human activities, including the incomplete combustion of fossil fuels or other organic materials. Most PAHs are sorbed to solid particles in the environment, which radically reduces the bioavailability and toxicity of the sorbed PAHs. PAHs have been shown to cause changes in liver enzymes and to perturb cell membranes, but in general, are not viewed as acutely toxic. Sublethal effects attributed to PAHs in aquatic animals include reduced reproductive ability and fertility, developmental abnormalities, delayed or retarded maturation, histological changes, and carcinogenesis (Neff 1985).

Dioxins and Furans

Polychlorinated dibenzo-p-dioxins (PCDDs) and polychlorinated dibenzofurans (PCDFs) are formed as by-products during the production of some herbicides, chlorophenols, and PCBs. They are also generated during the incineration of chlorinated compounds. There are 75 possible PCDD congeners and 135 possible PCDF congeners, and as with PCBs, their toxicity is dependent on the number and location of chlorine atoms. Additionally, dioxins and furans have large K_{ow} values which dictate their mobility and partitioning in environmental and biological media (Eisler 1986). Due to their low mobility and high persistence and lipophilicity, dioxins and furans are accumulated in sediments, soils and sludge, bioconcentrated in aquatic organisms, and bioaccumulated in adipose tissue of aquatic and terrestrial organisms (Geyer et al. 2002).

Substantial toxicity testing has identified 17 different 2,3,7,8-substituted PCDD and PCDF congeners (congeners reported to have dioxin-like toxicity with chlorine substitutions in at least the 2,3,7,8 positions) that present significant toxicological risk to humans and wildlife. The most toxic and frequently studied of these congeners is 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD). Toxicological effects associated with exposure to TCDD include: mortality, reproductive distress and failure, developmental effects, and decreased growth (Carey et al., 1998).

Herbicides and Organochlorine Pesticides

While some herbicides and organochlorine pesticides may exhibit acute toxicity, the most toxicity is due to long-term, chronic effects. These effects may include reduced fecundity, chronic lethality, neurological effects, cessation of feeding, and bone degeneration (Nimmo and McEwen 1994; Fontenot et al. 1999a,b). The mode of action for herbicides and organochlorine pesticides is not well understood, but they generally disrupt electrolyte balance in neurons and prevent them from conducting nerve impulses normally (Ware 1994). This manifests neurological effects such as reduced mobility, tremors, loss of equilibrium, convulsions, abnormal flexure, and lethargy or prostration. In addition, pesticides are well-known for causing eggshell thinning in birds and, thereby, reducing reproductive success (Newman 1998; Sample et al. 1996). In general, the organochlorine pesticides have very low water solubility and are considered insoluble (Nimmo 1985). However, they are soluble in polar solvents, and will preferentially move into fatty tissues. This fact, combined with the very slow breakdown rates, indicates that they will bioconcentrate into organisms in the lower levels of the food chain (such as worms) and will biomagnify into organisms in the higher levels of the food chain (such as raptors).

Polychlorinated Biphenyls

PCBs (like Aroclor 1260 and Aroclor 1254) were designed for use in “closed” electrical systems like transformers, capacitors, and vacuum pumps. These compounds typically have low solubility, and low vapor pressures, and therefore tend to sorb to solid, organic material in the aquatic environment. However, PCBs can be transported in the air, and have been known to be present in measurable quantities in remote areas, far from where they were produced or used (Niimi 1994). PCBs are known to bioaccumulate and biomagnify; however, they usually do not cause acute toxic responses, and their major effects are thought to be sublethal. In addition, PCBs are currently under scrutiny for endocrine disruption, and effects on the nervous and immune systems in higher order taxa within the food chain (Fontenot 1999b; Niimi 1994).

Inorganics

Many trace inorganics (e.g., cobalt, copper, chromium, iron, manganese, nickel, molybdenum, selenium, and zinc) are important in plant and animal nutrition, but the optimal concentration ranges are usually narrow (Leland and Kuwabara 1985). Other inorganics are nonessential, such as lead, cadmium, and mercury, and are toxic to receptors at very low concentrations.

Mechanisms of toxicity of inorganics to plants tend to depend on the nature of the reactivity of the inorganic itself (Efroymson et al. 1997a). They may alter or inhibit enzyme activity, interfere with deoxyribonucleic acid (DNA) synthesis or electron transport, or block uptake of essential elements. Little is known about mechanisms of toxicity of constituents in earthworms (Efroymson et al. 1997b).

Trace metals (such as arsenic, barium, beryllium, chromium, copper, lead, and zinc) are better understood than PAHs and PCBs with respect to their potential adverse impacts on aquatic wildlife (Newman 1998). Chromium, copper, and zinc are essential for healthy enzyme function, and some organisms cannot survive without these metals.

However, these naturally occurring constituents may cause adverse effects when exposure occurs at concentrations that significantly exceed background concentrations. The toxicity and effects of trace metals may be greatly influenced by pH, hardness, and organic carbon content of the water in which they occur (Leland and Kuwabara 1985).

Imbalances in the essential trace metals may cause a decrease in photosynthetic ability, poor spawning/hatching success, teratogenesis, susceptibility to predation and disease, reduced growth, mortality, histopathological changes, organ dysfunction of the liver or kidneys, neurological defects, changes in respiration and osmoregulation, and anemia. Some metals may bioaccumulate, but this mechanism is thought to be a less important ecological concern. Because these constituents are naturally occurring, many organisms have a capacity (albeit limited) to biotransform and/or eliminate naturally occurring inorganics (Newman 1998; Leland and Kuwabara 1985).

2.3.1.1.5 Description of Potentially Exposed Receptors

The identification of the categories of receptors most likely to be exposed helps to focus the SLERA. Potentially exposed receptors are designated based on the available habitat associated with the site. As described above and presented in the CSM, potentially exposed receptors include terrestrial wildlife (including mammals, birds, reptiles, and invertebrates), terrestrial plants, and aquatic biota (fish and invertebrates directly within the aquatic habitat).

This section also provides an evaluation of potential exposures to individual organisms of threatened and endangered species at the sites. Threatened and endangered species information was obtained from a biological survey that was conducted by the Virginia Department of Game and Inland Fisheries for the Radford Army Ammunition Plant in 1997-1998 (VDGIF 1999). The results of the VDGIF survey were also included in the RFAAP Integrated Natural Resource Management Plan (INRMP) (RAAP 2005). The VDGIF survey report included the identification of listed species observed on the plant property and their preferred habitats. Based on the information obtained from the survey, each Study Area was evaluated to determine whether suitable habitat for a listed species was present within that area.

Table A.2-16 presents the species listed in the biological survey (VDGIF 1999), their preferred habitats, and whether suitable habitat is present at one or more of the Study Areas (BDDT, BLA, IAA, RY, and WBG). This table shows that a total of 19 threatened, rare or watch-listed species were observed within the NRU during the 1997-1998 survey (VDGIF 1999). The list of 19 species is comprised of 16 terrestrial plants, 2 birds, and 1 terrestrial invertebrate. There were no federally listed species observed during the survey at the NRU. Three state threatened species were observed (i.e., Regal fritillary, Henslow's sparrow and Loggerhead shrike). Preferred habitats are not present at any of the SWMUs for any of these state threatened species, with two possible exceptions.

Grassland habitat present around the BLA could potentially provide suitable habitat for the butterfly Regal fritillary (*Speyeria idalia*). This butterfly was observed at the BLA and in the northern portions of the NRU during the 1997-1998 VDGIF survey.

The open field habitat present around the RY could potentially provide suitable habitat for Henslow's sparrow (*Ammodramus henslowii*). Four colonies were delineated in the NRU; all four were located in the northern portion of the NRU (i.e., north of the Northern Burning Ground) and not near the five Study Areas. Other sightings in the NRU were along the central grassland areas of the unit and not in close proximity with any of the Study Areas. Typically Henslow's sparrow habitat is comprised of tall dense vegetation with little or no woody vegetation (VDGIF 1999).

Based on this analysis, it is uncertain whether the two state listed species discussed above are present at any of the five ACOs, including the BLA and RY. The VDGIF survey was conducted ten years ago and species' occurrence may have been altered based on time and resource management at the NRU. However, if colonies of Henslow's sparrow and Regal fritillary do currently utilize areas of the BLA or RY, soil impacts at these Study Areas are generally near buildings, roads or other structures and not within open grassland areas (if available). Consequently, any potential exposure to the impacted areas would likely be minimal. Therefore, state listed threatened species are not considered a concern at the RFAAP-NRU.

2.3.1.1.6 Identification of Potentially Complete Exposure Pathways

A complete exposure pathway is "one in which the chemical can be traced or expected to travel from the source to a receptor that can be affected by the chemicals" (USEPA 2001c). Therefore, a constituent, its release and migration from the source, a receptor, and the mechanisms of toxicity of that constituent must be demonstrated before a complete exposure pathway can be identified. The table below summarizes the potential exposure routes for ecological receptors at the RFAAP-NRU (also illustrated on Figure 2-4).

Organism	Possible Exposure Routes
Terrestrial wildlife	Ingestion, direct contact, inhalation, and food chain
Terrestrial plants	Direct contact, uptake
Aquatic biota	Direct contact with, and uptake from, sediment and surface water and via food chain
Soil invertebrates	Direct contact with and uptake from sediment and soil

2.3.1.1.7 Selection of Generic Assessment and Measurement Endpoints

Assessment endpoints are the explicit expression of the ecological values to be protected (USEPA 1997c). The selection of assessment endpoints depends on knowledge of the receiving environment, knowledge about the constituents released (including their toxicological properties and the relevant concentrations), and understanding of the values that will drive risk management decisions (Suter et al. 1995a). Consistent with USEPA (1998) guidance, two elements are required to define an assessment endpoint: the specific valued ecological entity and the characteristic about the entity that is important to protect.

USEPA guidance provides that remedial actions should be designed not to protect organisms on an individual basis, but to protect local populations and communities of biota (USEPA 1999b). Thus, the first management principle for conducting an ERA is to provide a basis for selecting a response action “that will result in the recovery and/or maintenance of healthy local populations/communities of ecological receptors that are or should be present at or near the site” (USEPA 1999b). The USEPA guidance also notes, as an exception to this rule, that threatened and endangered species may be evaluated on an individual basis. This focus is justified on the basis that, given the stressed nature of a threatened and endangered population, effects on individuals could influence the local population.

Furthermore, it is important to realize that the size or space of an affected area is directly related to the potential for ecological exposure if ecological habitat is present. Spatial scale can be useful as a screening criterion if used in conjunction with other considerations, such as the valued ecological resources that may be present, current and future land use, the likelihood for COPEC migration from the site, and the proximity to a valued or sensitive ecological habitat. Spatial scale screening criteria are used widely in ERA guidance. The concept of spatial scale in ecological risk assessment is discussed in federal (USEPA) literature and guidance for determining if risk estimates are ecologically significant (USEPA 1998; 1997; 1994). While USEPA guidance notes the importance of examining spatial and temporal pattern of contaminants identified in low frequency and/or magnitude, it does not specify exact spatial scale criteria for a given site (USEPA 2001a). Although no information on spatial scale screening could be found in the Virginia DEQ guidance, the following spatial scale screening criteria are used by the following states: 1 to 2 acres for Minnesota (the smaller scale for bioaccumulative compounds); 1 acre for Texas, Louisiana, and Mississippi; 2 acres for Pennsylvania; and 2 acres or 1,000 square feet of sediments for Massachusetts (MPCA 1998; TCEQ 2001; MDEQ 1997; LDEQ 2003; PADEP 1998; MADEP 1996). This spatial scale criterion has often been referred to as *de minimus* because it is not expected to cause adverse effects to the population, community, or ecosystem, provided other conditions are met (Suter et al., 1995b; Henning and Shear 1998). These other conditions typically require that similar but unaffected habitat be available adjacent to the affected area, that sensitive habitat not be present within ¼ mile if the COPECs will migrate off site, and COPEC fate and transport must be unlikely to increase the spatial extent to greater than the current spatial extent. Provided these conditions are met, a 1-acre screening criterion is considered a conservative size criterion for determination of *de minimis* risk.

For the RFAAP-NRU, hypothetical assessment endpoints include the following:

- Sustainability of small mammal populations
- Sustainability of avian populations
- Sustainability of terrestrial plant communities
- Sustainability of soil invertebrate communities
- Sustainability of aquatic communities (i.e., fish and invertebrates)

Because direct measurement of assessment endpoints is often difficult or impossible, surrogate endpoints called measurement endpoints are used to provide the information necessary to evaluate whether the values associated with the assessment endpoint are being protected. A measurement endpoint is defined as a measurable ecological characteristic and/or response to a stressor (USEPA 1998). HQs typically serve as the measurement endpoints for SLERAs.

2.3.1.2 Screening-Level Ecological Effects Evaluation

The screening-level ecological effects evaluation involves the identification of ecological screening levels (ESLs) for each detected constituent found in each environmental medium at the RFAAP-NRU. ESLs are generally based on effects such as mortality and reproductive impairment, and are assumed to be widely applicable to sites around the United States for screening purposes (USEPA 1997c). For most constituents and receptors, the data available to generate ESLs are limited and related to effects on individual organisms, rather than populations or communities. Given these limitations, conservative assumptions are typically used to ensure that the ESLs are protective. ESLs available in the literature are screening values and do not constitute remediation goals, as they are sometimes based on highly conservative exposure assumptions and/or wildlife receptors that may not be applicable to a particular site. As such, their robustness and biological association with the assessment endpoint may be limited. However, conservative benchmarks provide a starting point for the SLERA in that they may provide an indication of the worst-case measure of the potential for adverse effects. Typically in a SLERA, ESLs are gathered from one or two sources leaving constituents without ESLs to be evaluated in the BERA. In this SLERA, ESLs were gathered from several sources during the modified SLERA to preserve effort in the BERA.

The following sources were considered in identifying soil ESLs for the SLERA:

- USEPA Ecological Soil Screening Levels (EcoSSLs) (USEPA, 2005b)
- Region 5 Ecological Screening Levels (USEPA 2003e)
- Oak Ridge National Laboratory (Efroymson et. al. 1997a,b; ORNL)

The following sources were considered in identifying sediment ESLs for the SLERA:

- Region 3 Sediment Screening Levels (USEPA 2008d)
- Oak Ridge National Laboratory (Jones et al. 1997)
- Region 5 Sediment Screening Levels (USEPA 2003e)
- USEPA Assessment and Remediation of Contaminated Sediments Program (ARCS) – used for aluminum ESLs

The following sources were considered in identifying surface water ESLs for the SLERA:

- Region 3 Fresh Water Screening Levels (USEPA 2008c)
- Oak Ridge National Laboratory (Suter and Tsao 1996)
- Region 5 Surface Water Screening Levels (USEPA 2003e)
- USEPA National Ambient Water Quality Criteria (USEPA 2008e)

Where multiple values were provided by sources, the lowest values were conservatively selected as is appropriate for a SLERA (USEPA 2000b; 1998; 1997c), if they were considered to have equal relevance and technical basis. The rationale for the selection of ESLs are provided in the following sections.

Further, in this step, constituents that have a tendency to bioaccumulate were also identified if they were designated as such by USEPA Region 3 (USEPA 2008c,d) or are included in the USEPA list of bioaccumulative compounds (USEPA 2000c).

Soil, sediment, and surface water ESLs for constituents detected onsite and their bioaccumulation potential are presented in Table A.2-18.

2.3.1.3 Step 2: Screening-Level Exposure Estimate and Risk Calculation

The screening-level exposure assessment is comprised of the identification of exposure estimates, risk calculations, and the evaluation of uncertainties (USEPA 2001a; 1997c). These components form the lines of evidence necessary to support the SMDP at the conclusion of the SLERA.

2.3.1.3.1 Identification of Screening-Level Exposure Estimates

Exposure estimates used for the modified SLERA were the maximum detected concentrations for each constituent (USEPA 2001a; 1997c). This conservative approach (i.e., using only the maximum detected concentrations) is appropriate for a screening-level effort.

The data summaries, including maximum concentrations and EPCs for soil, sediment, and surface water for the five Study Areas, whole body and fish fillet tissue data from the unnamed pond in the WBG, and for site-wide groundwater at the RFAAP-NRU are presented and discussed in the report sections devoted to those areas.

2.3.1.3.2 Screening-Level Risk Calculations

The screening level risk calculations provide an estimate of potential risk to ecological receptors. Risks to ecological receptors are calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the “maximum HQ”, is a highly conservative surrogate for the assessment endpoints. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse or significant ecological effects are unlikely (USEPA 1997c). Maximum HQs greater than 1 indicate that further evaluation is warranted to evaluate the potential for adverse ecological effects. Therefore, the constituents with HQs greater than 1 are identified as Constituents of Potential Ecological Concern

(COPECs) and carried forward into Step 3a of the BERA, except where the constituents are inorganics with maximum concentrations that are not greater than background levels. The background inorganics concentrations are based on calculated 95% UTLs generated from a facility-wide data set that incorporates both surface and subsurface soil from the RFAAP-MMA and the RFAAP-NRU. The calculated background concentrations are utilized to help differentiate between naturally occurring inorganic concentrations and concentrations resulting from human influence. The comparison with background is typically done in the first step of a BERA, however it was done here in the modified SLERA. Constituents were also identified as COPECs if no ESL was available or if the constituent was identified as bioaccumulative.

2.3.1.3.3 Evaluation of Uncertainties

SLERAs are designed to provide estimates of the risks that may exist for ecological receptors and to incorporate uncertainty in a precautionary manner. Uncertainty is “the imperfect knowledge concerning the present or future state of the system under consideration; a component of risk resulting from imperfect knowledge of the degree of hazard or of its spatial and temporal distribution" (USEPA 1997c). Uncertainties that may lead to either an overestimate or underestimate of risk are associated with each stage of risk assessment. Because the SLERA is intended to provide a precautionary approach to evaluating risks to ecological receptors, the majority of the SLERA uncertainties tend toward an overestimate of risk. Uncertainties associated with the SLERA are identified on Table A.2-17.

2.3.2 Scientific Management Decision Point

SMDPs represent critical steps in the ecological risk assessment process where risk management decision-making occurs. As was previously stated, the BERA is conducted for constituents with HQs that exceed 1 or are bioaccumulative and constituents that lack ESLs. Reporting occurs after either Step 2 or Step 3a, depending on the results obtained in Step 2, so that additional evaluation of risks can be evaluated if needed and reporting can be streamlined into a single report (USEPA, 2000a). Generally, the following types of decisions are considered at this SMDP:

- Whether the available information is adequate to conclude that ecological risks are negligible and, therefore, there is no need for remediation on the basis of ecological risk.

- Whether the available information is not adequate to make a decision at this point, and the ecological risk assessment process should continue.

- Whether the available information indicates a potential for adverse ecological effects, and a more thorough assessment or remediation is warranted.

The results of the screening-level risk calculations determine if the ERA should continue into the BERA as described in the following sections.

2.3.3 Baseline Ecological Risk Assessment

The BERA is designed to more realistically identify the nature and extent of ecological risks to support informed risk management decision-making (USEPA 2000b; 1997c). This approach contrasts with the SLERA, which is designed to conservatively rule out further evaluation of constituents and media that clearly do not pose a significant ecological risk. As indicated on Figures 2-2 and 2-3, the BERA process involves numerous steps. These steps are executed in a manner appropriate to the conditions at each individual site (USEPA 2000b; 1997c).

This section presents Step 3a of the BERA for the RFAAP-NRU, which is a refinement of the Step 2 exposure estimates and risk characterization, and focuses only on COPECs that were not eliminated in the SLERA. The refinement of the assessment presented in Step 1 and Step 2 is necessary to help focus and streamline further risk assessment activities on the constituents that pose the greatest potential risk to ecological receptors (USEPA 2001a; 2000b; 1997c). It is intended as an “incremental iteration of exposure, effects, and risk characterization” (USEPA 2001a). The outcome of this refined screening process is a list of COPECs to be retained for further evaluation in the BERA process.

The Step 3a discussion for the RFAAP-NRU is comprised of the following:

- Refinement of Constituents of Potential Ecological Concern,
- Refinement of Risk Calculations for Direct Contact COPECs,
- Assessment for Bioaccumulative COPECs, and
- Uncertainties.

Step 3a is followed by a SMDP that involves the reporting of results of Steps 1 through 3a.

2.3.3.1 Refinement of Constituents of Potential Ecological Concern

Typically, the process for refining the COPECs starts with 1) the comparison of maximum detected concentrations of naturally occurring inorganic constituents with background concentrations for each medium, and 2) the comparison of more realistic/refined EPCs (i.e., the lesser of the maximum detected concentration and the UCL) with the ESLs used in the SLERA. In some instances, these refinements were not applicable to the BERA. For example, comparison with background was not applicable because the modified SLERA already incorporated the comparison to background concentration for inorganics and comparison with background is generally not appropriate for organic constituents. Further, in some instances refined EPCs were not calculable due to limited data, therefore refined HQs were not able to be calculated.

2.3.3.2 Refinement of Risk Calculations for Direct-Contact COPECs

Risk calculations are typically refined by 1) using refined EPCs and 2) using refined ESLs. As mentioned in the section above, refined EPCs are UCLs on the mean versus maximum concentrations. There are numerous reasons to include alternative ESLs, most notably to fill any gaps in the set of ESLs used in the SLERA and to identify concentrations at which adverse effects are likely (e.g., probable effects values), rather than just possible. However, in this BERA, ESLs were not refined as the ESLs were already gathered from several sources during the initial SLERA and no further gaps could be filled.

The list of COPECs was refined in this BERA by refining the HQs. The refined HQs were calculated for the COPECs identified in the SLERA, using refined EPCs which is consistent with the approach for “incremental iteration of exposure, effects, and risk characterization” (USEPA 2001a; 1997c). Constituents identified as COPECs in the BERA that were bioaccumulative were evaluated using food chain models.

Further, it is well known that sediment toxicity of a substance is related to the bioavailable fraction of that substance in the pore water of sediments. Substances that are not sequestered by sediment ligands are neither bioavailable nor toxic to benthic organisms. It has been shown that both inorganics and organic compounds behave in that fashion. Organic compounds typically adhere to other organics in sediment such as humic acid. Inorganics can be sequestered by both organic matter in sediment and by sulfides present in the anoxic region of sediment.

Organic partitioning techniques have long been used to assess risk to aquatic communities from organic substances in sediment using measurements of total organic carbon (TOC) content in the sediment. Based on this information, the USEPA

(2003g) developed guidance for evaluating the bioavailability and toxicity of PAHs in sediments: *Procedures for Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: PAH Mixtures.* The ESBs represent defensible, numerical, and chemical-specific concentration limits of substances applicable across a range of sediment types to assess the extent of ecological risks of contaminated sediments, determine pollution control, and identify, prioritize, and implement appropriate cleanup levels (USEPA 2003g).

PAHs occur as mixtures rather than individual chemicals in the environment; ESBs for individual PAHs tend to be underprotective as they do not account for co-occurring PAHs. Therefore, ESBs are based on mixtures of PAHs in order to represent substantial and ecologically relevant protection of benthic organisms. The toxicity of mixtures of narcotic chemicals such as PAHs has been shown to be approximately additive. Therefore, the combined toxic contribution of PAHs in a mixture is the sum of the quotients of measured concentrations or final chronic values (FCVs) for each individual PAH in the sediment divided by its critical concentration (product of PAH-specific FVC and the respective TOC: water partition coefficient [K_{oc}]).

The quotient is called an Equilibrium Partitioning Sediment Benchmark Toxic Unit ($ESBTU_{FCV}$ or TU) and the summation as represented by $\Sigma ESBTU_{FCV}$ (total TU) is the HQ. If the HQ (total TUs) is equal to or less than one in a given sediment sample, the concentration of the PAH mixture in sediment is acceptable for the protection of benthic organisms. If the HQ exceeds one, the concentration of the PAH mixture in the sediment may not be acceptable for the protection of benthic organisms.

PAHs were identified as COPECs in this ERA, therefore, the ESBTU approach was used. The ESBTU approach was used to calculate a total TU which was compared to the benchmark of one. Where available, sample specific TOC was used otherwise the average total organic carbon (TOC) at the site was used instead. TOC ranged between 2.2% to 5.4% at the site and averaged at 3.4 percent.

USEPA's sediment quality guidelines are designed to be applied to a minimum of 34 PAHs, including alkylated PAHs. Default uncertainty factors (UFs) are provided for the assessment of smaller subsets of the total PAH concentration, in the absence of site-specific data for alkylated PAHs (USEPA 2003g). For this ERA, the use of a default UF was required, because alkylated PAHs were not measured in sediment samples collected from the Study Area and because the number of parent PAHs analyzed in sediment varied under 16. Therefore, a default UF of 2.75 was applied to the $\Sigma ESBTU_{FCV}$ to obtain an accurate estimation of the $\Sigma ESBGTU_{FCV,TOT}$ with 50% confidence.

2.3.3.3 Assessment and Measurement Endpoints for Bioaccumulative COPECs

Following the identification of bioaccumulative COPECs, the assessment and measurement endpoints at the RAAFP-NRU were refined. Additional assessment and measurement endpoint are summarized below:

Additional Assessment and Measurement Endpoints

Assessment Endpoint	Measurement Endpoint	Effects Measured
Survival and reproductive success of mammals exposed to bioaccumulative compounds in the terrestrial and aquatic food chain	Adverse changes in survival and reproduction as indicated by food chain modeling for short-tailed shrews and mink	NOAELs and LOAELs related to adverse chronic effects, such as reduced survival and reduced litter size
Survival and reproductive success of birds exposed to bioaccumulative compounds in the terrestrial and aquatic food chain	Adverse changes in survival and reproduction as indicated by food chain modeling for American robins and for the Great Blue Heron	NOAELs and LOAELs related to adverse chronic effects, such as eggshell thinning or reduced fledgling survival

NOAEL no observed adverse effect level.
LOAEL lowest observed adverse effect level.

2.3.3.3.1.1 Wildlife Receptors

The short-tailed shrew (*Blarina brevicauda*) and American robin (*Turdus migratorius*) were selected as terrestrial wildlife receptors and the mink (*Mustela vison*) and the great blue heron (*Ardea Herodias*) were selected as aquatic wildlife receptors for food chain modeling in the BERA. The shrew and robin were selected because these species are known to be susceptible to food chain exposures. Earthworms comprise a major component of the shrew and robin diets and earthworms are known to bioaccumulate persistent compounds (USEPA 1993a,b). The mink and heron were also selected because they are known to be susceptible to food chain exposures. Both species are piscivorous and fish are known to bioaccumulate persistent constituents. As such, if risks are not predicted for these species, then risks would not be expected for species with lesser exposures to bioaccumulative constituents (e.g., herbivores). In addition, dietary and toxicological information is available for these species, (e.g., USEPA 1993a,b; Sample et al. 1996) making food chain modeling feasible.

The short-tailed shrew is one of the most common mammals in America and is likely present at RFAAP-NRU. The short-tailed shrew also represents a conservative species for use in the BERA because it has a very high ingestion rate, and it consumes a high percentage of earthworms in its diet compared with other mammalian species. If risks are not predicted for this species, then risks should not be expected for species with lesser exposures to bioaccumulative constituents (e.g., herbivorous mammals).

The American robin is prolific throughout the United States, with a home range that includes Virginia. This bird is likely to forage in open areas and the ecotone between woodlands and open areas (i.e., edge habitat), and thus may be exposed to bioaccumulative COPECs at the RFAAP-NRU. The American robin also can be used as a surrogate species to represent other species that are likely to be present at the RFAAP-NRU and in the adjacent woodlands, but for which less exposure-related and toxicological information is available. Risks to the American robin could identify potential risks to other species with similar diets.

Much like the shrew, the mink is also a common mammal in North America, and would likely inhabit parts of Virginia including the RFAAP-NRU. Mink are found in a variety of aquatic habitats, including waterways such as rivers, streams, lakes, and ditches, as well as swamps, marshes, and backwater areas. Mink hunt primarily along the shorelines and emergent vegetation, consuming whatever prey is most abundant. While their diet can include mammals, fish, amphibians, crustaceans, birds, reptiles, and insects, typically mink found in a stream habitat like the ones predominantly found at the RFAAP-NRU feed mainly on fish, plants, and small mammals (USEPA 1993a,b). Similar to the shrew, if risks are not predicted for this species, then risks should not be expected for species with lesser exposures to bioaccumulative constituents.

The great blue heron is the largest member of the wading bird group in North America. This species can be found in a variety of aquatic habitats, including freshwater lakes and rivers, brackish marshes, lagoons, mangroves, and coastal wetlands. Fish make up the majority of the heron's diet, but great blues also eat amphibians, reptiles, crustaceans, insects, birds, and mammals (USEPA 1993a,b). The great blue heron can be used as a surrogate species to represent other species that are likely to be present at the RFAAP-NRU and in the adjacent aquatic habitats, but for which less exposure-related and toxicological information is available. Risks to the great blue heron could identify potential risks to other species with similar diets.

Wildlife receptor exposure parameters were gathered from USEPA (1993a,b) and from literature sources as applicable. Wildlife receptor exposure parameters are summarized in Table A.2-19.

2.3.3.4 Food chain Modeling

The food chain modeling evaluation of a BERA includes exposure assessment and effects assessment. The exposure assessment describes the EPCs for the COPEC and discusses the types of exposure models and their parameters. The effects assessment describes the types of receptor- and COPEC-specific toxicological benchmarks that were used in the BERA.

2.3.3.4.1 Exposure Assessment

Exposure assessment describes the potential contact of COPECs with ecological communities or receptors. The objective of the exposure assessment is to provide an exposure profile that identifies ecological communities or receptors and exposure pathways, and describe the intensity and spatial and temporal extent of contact of ecological communities or receptors to COPECs. The receptors that were evaluated are consistent with the identified Measurement endpoints. The intensity, spatial, and temporal extent of contact to COPECs are described by the EPCs, exposure assumptions, and intakes (or dose estimates), as discussed in the following sections.

2.3.3.4.1.1 Exposure Point Concentrations

Two types of exposure concentrations were used in the BERA. For the maximum risk estimates, maximum concentrations were used as exposure concentrations while for the refined scenario, EPCs based on the lower of the maximum and the UCL (where calculable) were used as the exposure concentrations. Methods used to calculate EPCs are outlined in Section 2.

2.3.3.4.1.2 Exposure Parameters

Exposures to ecological communities are expressed in terms of abiotic media concentrations, whereas exposures to ecological receptors (mammals and birds) are expressed in terms of dose. For ecological receptors, numerous exposure parameters such as contact rates, body weights, and absorption factors were defined prior to estimation of exposure dose. Exposure and intake parameters are defined on the basis of available literature information and best professional judgment. Wildlife receptor exposure parameters were gathered from USEPA (1993a,b) and from literature sources as applicable. Wildlife receptor exposure parameters are summarized in Table A.2-19.

2.3.3.4.1.2.1 Body Weight

Body weights (BWs) for mammals and birds expressed in kilograms (kg) were based on the average weights for male and female (combined) for both adults and juveniles, consistent with USEPA guidance (USEPA 1997c). These BWs were obtained from the USEPA's Wildlife Exposure Factors Handbook (USEPA 1993a) for all receptors.

2.3.3.4.1.2.2 Dietary Composition

The composition of the diet for mammals and birds expressed as a fraction of the total diet were based on information on the feeding guilds for each of the species. Consistent with USEPA guidance (USEPA, 1997c), it was assumed that the diet for each receptor consists of 100% of the primary food source (i.e., biota) initially in the maximum scenario and then was refined to reflect actual diet proportions in the refined scenario. The proportions of material ingested (biota, soil) were based on available literature (USEPA 1993a; Beyer et. al.1994).

2.3.3.4.1.2.3 Food Ingestion Rates

Total food ingestion rates (IRf) for mammals and birds expressed in kilograms per day (kg/day) were obtained from available literature (USEPA 1993a; Beyer et. al. 1994). If an IRf was not available for a receptor, an IRf was calculated as a function of body weight using allometric equations (Nagy 2001).

2.3.3.4.1.2.4 Home Range and Area Use Factors

Home range is defined as the geographic area encompassed by an animal's activities (except migration) during a specified time and the area use factor (AUF) is unitless and represents the fraction of the exposure area for the receptor represented by the area of contamination. The AUF is generally calculated by dividing the area of contamination by the home or foraging range of the receptor. While the home ranges of birds and mammals, such as heron and mink, can be quite substantial, it was conservatively assumed that each receptor spends 100 percent of its time foraging within the area of contamination. This likely resulted in substantially overestimated risks for these species.

2.3.3.4.1.3 Assessment of Bioaccumulation

Bioaccumulative COPECs were identified and were assessed via the food chain modeling in both the terrestrial and aquatic food chains. Food chain models predict detrimental effects to wildlife survival and reproduction. Intake measurements are a conservative estimate of exposure through the food chain. Food sources for terrestrial model include soil, vegetation, invertebrates and small mammals and food sources for aquatic food chains include sediment, surface water, vegetation, invertebrates, small mammals, and fish. Measured concentrations in the food sources were used where available (i.e., soil, sediment, and surface water in all Study Areas and whole body fish tissue concentrations in the unnamed pond in the WBG). To estimate concentrations in plants, invertebrates and small mammals, and fish, bioconcentration factors (BCFs) and bioaccumulation factors (BAFs) were used. BCFs describe the transfer (uptake) of a constituent from environmental media into tissues of vegetation and organisms in the food chain, while BAFs describe the transfer (uptake) of a constituent from dietary tissue into tissues of organisms in the food chain. The following medium-biota BCFs and BAFs were developed:

- Soil-to-Vegetation Uptake ($BCFsl_v$)
- Soil-to-Invertebrate Uptake ($BCFsl_i$)
- Soil-to-Mammal/Bird Uptake ($BAFsl_{mam}$)
- Sediment-to-Plant Uptake ($BCFsed_{plant;}$ dw)
- Sediment-to-Invertebrate ($BCFsed_{inv}$)
- Sediment-to-Mammal ($BAFsed_{mam}$)
- Sediment-to-Fish ($BAFsed_{fish}$)

The soil BCFs and BAFs for the COPECs are identified in Table A.2-20 and the sediment BCFs and BAFs are presented in Table A.2-21, and include the sources where each value was obtained.

2.3.3.4.2 Intake Assessment

Daily intake represents an estimate of a COPEC dose that a receptor might receive on a daily basis, and is calculated by summing intakes for assumed exposure pathways (i.e., dietary composition types) for each receptor. Intake is calculated by combining the concentration of a COPEC in an exposure media (soil/sediment, food, and water) with applicable receptor exposure assumptions. To estimate the concentration of a bioaccumulative COPEC in a food source (vegetation, invertebrates, small mammals, fish), bioaccumulation factors (BAFs) are used. The sections below discuss receptor exposure parameters and BAFs used to estimate intake for wildlife receptors at the site.

2.3.3.4.3 Effects Assessment

Food chain modeling requires the use of toxicity reference values (TRVs) to describe the potential toxicity of the COPECs to ecological receptors. The TRV is the assumed safe dose (in milligrams per kilogram body weight per day [mg/kg-BW-day]) to the receptor species. Calculation of TRVs generally relies on the use of laboratory toxicity benchmarks for laboratory species, as data on wildlife species usually are not available. Ecotoxicity benchmarks are typically reported as no observed adverse effect levels (NOAELs) and lowest observed adverse effect levels (LOAELs) for the laboratory species upon which testing was conducted.

For mammalian receptors, NOAELs and LOAELs are adjusted to account for the differences in body weights between the species tested and the receptor species (Sample et al. 1996). The extrapolation is based on the premise that metabolic function and toxicity are related to body size (i.e., constituents are less toxic to smaller animals because they metabolize and excrete constituents faster). Therefore, mammalian toxicity values were derived from toxicity values from laboratory studies using the Sample et al. (1996) equation. Toxicity values for birds are not adjusted to reflect the different weights of test species and wildlife receptor species (Sample et al. 1996).

Avian and mammalian TRVs used in this BERA are presented in Tables A.2-22, and A.2-23, respectively.

2.3.3.5 Risk Characterization

Potential risk was estimated using HQs, which were the ratio of the concentration in a given media to the screening level in the media. For the assessment endpoint on higher trophic levels, the HQ was the ratio of the daily intake to the TRV. Equations used for risk characterization including intake equations and equation used to estimate mammalian and avian TRVs are presented in Table A.2-24.

2.3.3.5.1 Maximum Risk Estimates

Maximum risk estimates were calculated by combining maximum concentrations and conservative (maximum) exposure assumptions in the food chain models.

2.3.3.5.2 Refined Risk Estimates

Refined risk estimates were calculated by combining EPCs, based on the UCL where calculable and maximum concentrations if not, and screening levels or refined exposure assumptions in the food chain models.

2.3.3.6 Refined Uncertainties

A BERA is designed to evaluate potential risks for wildlife by incorporating iterative changes that reduce uncertainty (when possible) and provides more realistic exposure assumptions. Uncertainties associated with the BERA are summarized on Table A.2-17.

2.3.3.7 Scientific Management Decision Point

As discussed previously, the SMDP represents a critical step in the ecological risk assessment process where risk management decision-making occurs (Figures 2-2 and 2-3). An SMDP occurs after Step 2 and Step 3a (if necessary based on the results of Step 2), so that additional evaluation of risks can be conducted if needed and reporting can be streamlined into a single report (USEPA 2000b). Generally, the following types of decisions are considered at this SMDP:

- Whether the available information is adequate to conclude that ecological risks are negligible and, therefore, there is no need for remediation to mitigate ecological risks.

- Whether the available information is not adequate to make a decision at this point, and the ecological risk assessment process should continue.

- Whether the available information indicates a potential for adverse ecological effects, and a more thorough assessment or remediation is warranted.

- If the SMDP indicates that either information is not adequate to make a decision or information indicates a potential for adverse ecological effects, then the ERA process should continue.

3. Building Debris Disposal Trench Area

3.1 Site Description and History

The BDDT is located in the southern portion of the RFAAP-NRU, south of A Avenue. The trench was formerly an ephemeral unlined natural drainage channel that had eroded into the clay surficial soil. The trench channels surface water runoff from the surrounding area down the length of the trench towards the unnamed creek (UNC-NRU) which passes through the area at the base of the BDDT. An approximately 600 ft long portion of the natural depression formed by the trench was previously utilized for the disposal of miscellaneous building debris derived from the dismantling of various structures at the RFAAP-NRU. The building debris consisted of concrete, wood, and rusted and broken drums of a black, tarry substance believed to be roofing tar. The building debris and any visibly stained soil were removed from the trench in 1998. The excavated material was replaced with clean fill and the trench was lined with a geotextile fabric and filled with riprap to minimize the potential for erosion. The area downgradient of the trench did not contain any debris and is covered with a thick grass groundcover.

3.2 Physical Setting

Rolling, grass-covered hills with incised drainage channels provide the setting for the BDDT. The trench runs from north to south between two hills and is approximately 650ft long by 15 ft wide. The head of the trench begins at A Avenue, at an approximate elevation of 2,000 ft above mean sea level (amsl) and slopes downward to the south ending an elevation of approximately 1970 ft amsl. The area downgradient of the trench widens into an open area between the two hills before ending at a small unnamed creek (UNC-NRU) that runs through the southern portion of the RFAAP-NRU. The elevation of the creek bed downgradient of the BDDT is approximately 1960 ft amsl.

The surface soils in the BDDT area generally consist of an organic-rich silty-clay approximately 1 ft deep, which is typical of topsoil throughout the vegetated areas of the RFAAP-NRU. A silty-clay layer with a lower organic content, typical of the Carbo Unit, underlies the surface soils. This unit ranges from strong brown to brownish yellow in color and extends to approximately 4 ft bgs. Bedrock is generally encountered around 5.5 ft bgs, with a saprolitic weathering zone extending from 4 ft bgs to refusal at the bedrock surface. The reported depths are approximate, since the bedrock surface is variable and consists of weathered shale interbedded with layers of limestone and dolomite. Bedrock outcrops are visible along the length of the trench.

3.3 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. Risk assessment datasets for soil, sediment, and surface water for the BDDT were prepared then summarized and statistically analyzed per methods described in Section 2. Risk assessment datasets summaries highlighting: the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPC are presented in Tables A.3.Data-1 through A.3.Data-5.

As discussed in Section 5.1 of the RI, previous site restoration activities mitigated the source area and potential exposure pathways along the portion of the trench that is now covered by a geotextile liner and riprap. Although the soils in the riprap covered portion of the BDDT are not currently accessible for either human or wildlife exposures, the data from these locations were included in the soil dataset to evaluate potential risks if the rip rap was to be removed in the future so that the soils under it would become accessible. Because the source of COPCs in the rip rap area (the ditch) differed from the source in the remainder of the BDDT, an additional analysis was conducted to determine if potential risks would differ if the soils in that portion of the BDDT were to become accessible in the future and future activities were focused on that area (Section 3.3.4.4).

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with constituents detected in soil, sediment and surface water samples collected at the BDDT. The risk assessment approach follows the Radford Army Ammunition Plant Final Master Work Plan (URS 2003) and the information included in Section 2 of this appendix.

3.4 Human Health Risk Assessment

3.4.1 Selection of Constituents of Potential Concern

This section discusses the selection of COPCs for the HHRA for each medium at the BDDT.

3.4.1.1 Surface Soil

Surface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.3.HHRA-1 presents the selection of surface soil COPCs for the human health risk assessment. As summarized in Table A.3.HHRA-1, 13 constituents were identified as COPCs in surface soil as follows:

Three VOCs (1,2,4-trimethylbenzene; m,p-xylene, and xylenes [total]) were detected in surface soil. All of these constituents were detected in concentrations below the USEPA (2009a) residential soil RSL values, and as a result, were not identified as COPCs in surface soil.

Two SVOCs (carbazole and dibenzofuran) were detected in surface soil. While dibenzofuran was detected in concentrations below the USEPA (2009a) residential soil RSL value, no value was available for carbazole; as a result, this constituent was identified as a COPC for surface soil.

Four herbicides (2,4-D; dalapon; dicamba; and MCPP) were detected in surface soil. Only MCPP was detected in concentrations above the USEPA (2009a) residential soil RSL value and was identified as a COPC for surface soil.

Two pesticides (4,4'-DDD and methoxychlor) were detected in surface soil; however, both of these constituents were detected in concentrations below the USEPA (2009a) residential soil RSL values.

Eight PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; indeno[1,2,3-cd]pyrene; and naphthalene) were detected at concentrations greater than the USEPA (2009a) residential soil RSL values and were identified as COPCs for surface soil.

Twenty-two inorganics were detected in surface soil. Four constituents (calcium, magnesium, potassium, and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Cobalt, iron, and manganese were identified as COPCs for surface soil, as they exceeded both their residential RBCs and their background concentrations.

3.4.1.2 Combined Surface and Subsurface Soil

Combined surface and subsurface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.3.HHRA.2 presents the selection of the combined surface and subsurface soil COPCs for the human health risk assessment. As summarized in Table A.3.HHRA.2, 13 constituents were identified as COPCs in combined surface and subsurface soil as follows:

Building Debris Disposal Trench Area

Three VOCs (1,2,4-trimethylbenzene; m,p-xylene, and xylenes [total]) were detected in combined surface and subsurface soil; however, all of these constituents were detected in concentrations below the USEPA (2009a) residential soil RSL values and were not identified as COPCs for combined surface and subsurface soil.

Two SVOCs (carbazole and dibenzofuran) were detected in combined surface and subsurface soil. Dibenzofuran was detected in concentrations above the residential RSL value and no USEPA (2009a) residential soil RSL value was available for carbazole; as a result, both constituents were identified as COPCs for combined surface and subsurface soil.

Four herbicides (2,4-D; dalapon; dicamba; and MCPP) were detected in combined surface and subsurface soil. Only MCPP was detected in concentrations above the USEPA (2009a) residential soil RSL value and was identified as a COPC for combined surface and subsurface soil.

Two pesticides (4,4'-DDD and methoxychlor) were detected in combined surface and subsurface soil; however, both of these constituents were detected in concentrations below the USEPA (2009a) residential soil RSL values.

Eighteen PAHs (1-methylnaphthalene; 2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in combined surface and subsurface soil. Eight of these detected constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; indeno[1,2,3-cd]pyrene; and naphthalene) were detected at concentrations greater than the USEPA (2009a) residential soil RSL values and were identified as COPCs for combined surface and subsurface soil.

Twenty-two inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; sodium; thallium; vanadium; and zinc) were detected in combined surface and subsurface soil. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Six of these constituents (aluminum; arsenic; cobalt; iron; manganese; and vanadium) were detected at maximum concentrations greater than the USEPA (2009a) residential soil RSL values; however, aluminum, arsenic, and vanadium were detected below the background concentrations. As a result, only

Building Debris Disposal Trench Area

cobalt, iron, and manganese were identified as COPCs for combined surface and subsurface soil.

3.4.1.3 Sediment

Sediment COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.3.HHRA.3 presents the selection of sediment COPCs for the human health risk assessment. As summarized in Table A.3.HHRA.3, 12 constituents were identified as COPCs in sediment as follows:

Six VOCs (acetone; carbon disulfide; methylene chloride; p-isopropyltoluene; toluene; and trichloroethene) were detected in sediment; however, all of these constituents were below the USEPA (2009a) residential soil RSL values.

Two SVOCs (4-methylphenol and di-n-butylphthalate) were detected in sediment; however, both of these constituents were detected in concentrations below the USEPA (2009a) residential soil RSL values.

Six pesticides (4,4'-DDD; 4,4'-DDE; 4,4'-DDT; delta-BHC; alpha-chlordane; and dieldrin) were detected in sediment; however, all of these constituents were detected in concentrations below the USEPA (2009a) residential soil RSL values.

Eighteen PAHs (1-methylnaphthalene; 2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in sediment. Five of these constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene) were detected at concentrations greater than the USEPA (2009a) residential soil RSLs and were identified as COPCs for sediment.

Twenty-one inorganics (aluminum; antimony; arsenic; barium; beryllium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; silver; sodium; thallium; vanadium; and zinc) were detected in sediment. Seven of these constituents (aluminum; arsenic; cobalt; iron; manganese; thallium; and vanadium) were detected at concentrations greater than the USEPA (2009a) residential soil RSL values, and four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients. Consequently, only aluminum, arsenic, cobalt, iron, manganese, thallium, and vanadium were identified as COPCs for sediment.

Building Debris Disposal Trench Area

3.4.1.4 Surface Water

Surface water COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for tap water. Table A.3.HHRA.4 presents the selection of surface water COPCs for the human health risk assessment. As summarized in Table A.3.HHRA.4, four constituents were identified as COPCs in surface water as follows:

Three VOCs (bromodichloromethane; carbon disulfide; and chloroform) were detected in surface water. Two these constituents, including bromodichloromethane and chloroform, were detected above the USEPA (2009a) tap water RSL values and were identified as COPCs for surface water.

One SVOC (di-n-butylphthalate) was detected in surface water; however, this constituent was detected in concentrations below the USEPA (2009a) tap water RSL value, and as a result, was not identified as a COPC for surface water.

Three pesticides (4,4'-DDT; dieldrin; and endrin ketone) were detected in surface water. Of these three constituents, only dieldrin was detected in concentrations above the USEPA (2009a) tap water RSL and was identified as a COPC for surface water.

Five PAHs (2-methylnaphthalene; acenaphthene; acenaphthylene; fluorene; and naphthalene) were detected in surface water. All five of these constituents were detected in concentrations below the USEPA (2009a) tap water RSL values and were not identified as COPCs for surface water.

Fifteen inorganics (aluminum; antimony; barium; calcium; copper; iron; lead; magnesium; manganese; nickel; potassium; silver; sodium; thallium; and zinc) were detected in surface water. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Of these detected constituents, thallium was detected at a maximum concentration above the USEPA (2009a) tap water RSL value. As a result, only thallium was identified as a COPC for surface water.

3.4.2 Summary of Selected Constituents of Potential Concern

Fourteen constituents were selected as COPCs in surface soil and combined surface and subsurface soil at the BDDT, including one SVOC (carbazole), eight PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; indeno[1,2,3-cd]pyrene; and naphthalene), one herbicide (MCPP), and four inorganics (cobalt; iron; lead; and manganese).

Building Debris Disposal Trench Area

Twelve constituents were selected as COPCs in sediment at the BDDT, including five PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene), and seven inorganics (aluminum; arsenic; cobalt; iron; manganese; thallium; and vanadium).

Four constituents were selected as COPCs in surface water at the BDDT, including two VOCs (bromodichloromethane and chloroform), one pesticide (dieldrin), and one inorganic (thallium).

3.4.3 Determination of Exposure Point Concentrations

Fourteen constituents were selected as COPCs in both surface soil and combined surface and subsurface soil, twelve constituents were selected as COPCs in sediment, and four constituents were selected as COPCs in surface water because the maximum detected concentrations were greater than the corresponding USEPA (2009a) RSL or no RSL was available. The EPCs for these COPCs are summarized in Table A.3.HHRA.5.

3.4.4 Human Health Risk Characterization

The physical and chemical properties and toxicity values used to evaluate excess lifetime cancer risks and non-cancer hazards are presented in Tables A.2-3 through A.2-9. The exposure assumptions used to evaluate potentially exposed receptors are presented in Table A.2-10. The equations used in the risk characterization calculations are presented in Tables A.2-11 through A.2-15. The soil, sediment, and surface water COPCs were evaluated for direct contact. VOCs identified as COPCs in the BDDT were also evaluated for inhalation via vapor migration into hypothetical future buildings. Potential exposures of a site worker, construction worker and hypothetical future adult and child residents were evaluated for the BDDT. The excess lifetime cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the BDDT are summarized in the tables and subsections below.

3.4.4.1 Site Worker

A current or future site worker could be present at the BDDT area, and could be exposed to surface soil, sediment, surface water, or combined surface and subsurface soil via vapor migration to indoor air. The ELCR and non-cancer hazard index for site worker exposure to each medium are presented in Tables A.3.HHRA-6 through A-3.HHRA-9, and are summarized in Table A.3.HHRA-19.

Building Debris Disposal Trench Area

The total cumulative ELCR for site workers exposed to surface soil, sediment, surface water, and air at the BDDT is 7×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.6, which is less than the benchmark of 1.

3.4.4.2 Hypothetical Future Construction Worker

A hypothetical future construction worker could be present at the BDDT area, and could be exposed to combined surface and subsurface soil. The ELCR and non-cancer hazard index for hypothetical future construction worker exposure to soil are presented in Table A.-HHRA-10.

The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the BDDT was 2×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 1, which is equal to the benchmark of 1. When the HI is segregated into target site and critical effects, all hazards are less than the benchmark of 1.

3.4.4.3 Hypothetical Future Residents

A hypothetical future resident could be present at the BDDT area, and could be exposed to combined surface and subsurface soil, sediment, surface water or combined surface and subsurface soil via vapor migration to indoor air. The ELCRs and non-cancer hazard indices for a hypothetical future resident's exposure to each medium are presented in Tables A.3.HHRA-11 through A.3-HHRA-18, and are summarized in Table A.3.HHRA-19, where the cancer risks for the adult and child resident are summed to to provide the estimated ELCR over the entire 30-year exposure period.

The total cumulative ELCR for a hypothetical resident exposed to combined surface and subsurface soil, sediment, surface water, and air at the BDDT is 4×10^{-4}, which is above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The COPC that contributed the most to ELCR (i.e., the risk driver), is benzo(a)pyrene.

The total cumulative HI for hypothetical future adult residents is 0.6, which is less than than the benchmark of 1.

The total cumulative HI for hypothetical future child residents is 5, which is greater than the benchmark of 1. When the HI is segregated into target site and critical effects,

Building Debris Disposal Trench Area

hazards were only greater than the benchmark of 1 in the skin due to the presence of cobalt. Cobalt may be present due to naturally occurring conditions at the BDDT.

3.4.4.4 Future Exposure to Soils Under the Rip rap

In order to evaluate the risks specific to the rip rap portion of the BDDT, EPCs, ELCRs, and HIs were calculated for each receptor using the data available for the riprap area, as indicated in Tables A.3.Data-1 through A.3.Data-5. The sample locations that are located under the rip rap include DTSB1, DTSB2, DTSB3, DTSB4, DTSB5, DTSB6, DTSB7, DTSB8, DTSB9, DTSB10, DTSB11, DTSB12, DTSB13, DTSB14, DTSB15, DTSB16, DTSB17, DTSB18, DTSB19, DTSB20, DTSB21, DTSB22, DTSB23, DTSB35, DTSB36, DTSB37, DTSB38, DTSB39, DTSB40, DTSB41, DTSB42, DTSB43, DTSB44, and DTSB45. EPCs for the subset of BDDT data corresponding to the riprap area are presented in Table A.3.HHRA-5. Because no subsurface soil samples were collected at the rip rap area, unique EPCs were calculated only for surface soils, and calculated risks represent exposure to surface soils only.

The ELCR and non-cancer hazard index for site worker exposure to each medium are presented in Tables A.3.HHRA-20 and A-HHRA-21, and are summarized in Table A.3.HHRA-27. The total cumulative ELCR for site workers exposed to surface soil, sediment, surface water, and air at the rip rap portion of the BDDT is 2×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.3, which is less than the benchmark of 1.

The ELCR and non-cancer hazard index for hypothetical future construction worker exposure to soil are presented in Table A.-HHRA-22. The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the riprap portion is 2×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 0.4, which is below the benchmark of 1.

The ELCR and non-cancer hazard index for hypothetical future adult or child resident exposure to each medium at the riprap portion of the BDDT are presented in Tables A.3.HHRA-23 through A.3-HHRA-26, and are summarized in Table A.3.HHRA-27.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, surface water, and air is 3×10^{-4}, which is above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future adult residents is 0.4, which is less than the benchmark of 1. The total cumulative HI for hypothetical future child residents is 2, which is greater than the benchmark of 1. When the HI is segregated into target site and critical effects, all hazards are less than the benchmark of 1.

EPCs, ELCRs, and HIs for the riprap portion of the BDDT are generally lower than those for the BDDT as a whole, indicating that the riprap area would not pose a higher risk or hazard if the rip rap area were to be used in the future. This analysis is highly conservative as it presumes that future individuals would spend all of their time in the rip rap area alone. Given the nature of this area, this is not likely to occur.

3.4.5 Human Health Risk Summary

Table A.3.HHRA-19 summarizes the calculated cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the BDDT. Table A.3.HHRA-27 summarizes the same information for the riprap portion only. As shown in the table below, the total ELCR values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below or within the benchmark range of 10^{-6} to 10^{-4} for cancer risk except for the hypothetical future resident. Therefore, it is unlikely that significant cancer risk would occur either from exposure to the BDDT as a whole or from exposure in the rip rap area only, except to the hypothetical future resident.

Building Debris Disposal Trench Area

Summary of Calculated ELCRs for Receptor Exposure Scenarios for Entire BDDT and Riprap Portion Only

RECEPTOR/ EXPOSURE MEDIUM – SCENARIO	**ELCR at BDDT**	**ELCR for Rip rap portion**
Site Worker		
Surface Soil - Direct Contact	5×10^{-5}	2×10^{-5}
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	NA	NA
Sediment – Wading	1×10^{-5}	NA
Surface Water – Wading	4×10^{-7}	NA
TOTAL SITE RISKS (Site Worker):	**7×10^{-5}**	**2×10^{-5}**
Hypothetical Future Construction Worker		
Combined Surface and Subsurface Soil - Direct Contact	2×10^{-6}	2×10^{-6}
TOTAL SITE RISKS (Construction Worker):	**2×10^{-6}**	**2×10^{-6}**
Hypothetical Future Resident		
Combined Surface and Subsurface Soil - Direct Contact	4×10^{-4}	3×10^{-4}
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	NA	NA
Sediment – Wading	5×10^{-5}	NA
Surface Water – Wading	2×10^{-7}	NA
TOTAL SITE RISKS (Resident):	**4×10^{-4}**	**3×10^{-4}**

As shown in the table below, the total HI values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are at or below the benchmark of 1 for non-cancer hazard for both the entire BDDT and the riprap portion only, with the exception of hypothetical future child resident exposure to combined surface and subsurface soil. When the HIs are segregated into target site and critical effects, hazards were greater than the benchmark of 1 in the skin for hypothetical future child resident exposure to the entire BDDT. Cobalt is the constituent exceeding the benchmark in this exposure scenario.

Building Debris Disposal Trench Area

Summary of Calculated HIs for Receptor Exposure Scenarios for Entire BDDT and Riprap Portion Only

RECEPTOR/ EXPOSURE MEDIUM – SCENARIO	HI at BDDT	HI for Riprap portion
Site Worker		
Surface Soil - Direct Contact	0.5	0.1
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	0.04	0.1
Sediment – Wading	0.02	NA
Surface Water – Wading	0.04	NA
TOTAL SITE RISKS (Site Worker):	**0.6**	**0.3**
Hypothetical Future Construction Worker		
Combined Surface and Subsurface Soil - Direct Contact	1	0.4
TOTAL SITE RISKS (Construction Worker):	**1**	**0.4**
Hypothetical Future Adult Resident		
Combined Surface and Subsurface Soil - Direct Contact	0.5	0.2
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	0.06	0.2
Sediment – Wading	0.04	NA
Surface Water – Wading	0.01	NA
TOTAL SITE RISKS (Adult Resident):	**0.6**	**0.4**
Hypothetical Future Child Resident		
Combined Surface and Subsurface Soil - Direct Contact	4	2
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	0.06	0.2
Sediment – Wading	0.3	NA
Surface Water – Wading	0.04	NA
TOTAL SITE RISKS (Child Resident):	**5**	**2**

Potential exposure to the COPCs during industrial use of the BDDT and riprap portion only resulted in ELCRs and HIs within the target risk range and equal to, or less than, the hazard benchmark.

The results of the risk assessment indicate that residential redevelopment of the BDDT area as a whole or the rip rap portion alone would result in risks or hazards outside the regulatory benchmarks. The cancer risk driver for hypothetical future residents is benzo(a)pyrene. Exposure to cobalt, which was estimated using the maximum detected concentration, resulted in slightly elevated non-cancer hazards for hypothetical child residents. All of the other detections of cobalt at the BDDT were within the background range.

3.5 Ecological Risk Assessment

The purpose of the ERA is to evaluate whether ecological receptors may be adversely impacted by exposure to site-related constituents detected in surface soil, sediment, and surface water at the BDDT. The ERA approach is based on the Master Work Plan (URS 2003). The ERA was conducted in a manner consistent with Virginia policy and USEPA guidance for ecological risk assessment (USEPA 2001a; 2000b; 1997c). This ERA is intended to provide input for risk management decision-making for the BDDT, while maintaining a conservative approach protective of wildlife populations and communities. In accordance with USEPA guidance, the ERA for the BDDT commenced with a SLERA and then concluded with a BERA (USEPA 1997c).

This section summarizes the occurrence of constituents in each medium and identifies COPECs at the BDDT for the ERA; identifies the potential ecological exposure scenarios relevant to the BDDT; and presents the estimated ecological risks associated with the identified COPECs and the relevant ecological exposure scenarios at the BDDT. Methodologies for data summary and selection of COPECs, exposure assessment, and toxicity assessment for the ERA were presented in Section 2.4.

3.5.1 Selection of Constituents of Potential Ecological Concern

This section discusses the selection of COPECs for each medium. Risks to ecological receptors are calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the hazard quotient (HQ), is a highly conservative surrogate for the assessment endpoints identified in Section 2.4. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse ecological effects are unlikely (USEPA 1997c). HQs greater than 1 indicate that further evaluation is warranted. Therefore, the constituents with HQs greater than 1 are carried forward as COPECs into the BERA. Because the majority of the ESLs measure direct exposures and do not take into account exposures to upper trophic level species, chemicals identified as bioaccumulative were also carried forward as COPECs regardless of whether or not the associated HQ was greater than 1. Finally, as previously described, concentrations of inorganic constituents in soil were compared to background soil concentrations; those with concentrations below background were not considered as COPEC. The COPEC selection process for the BDDT is summarized below.

Building Debris Disposal Trench Area

3.5.1.1 Surface Soil

Surface soil COPECs were selected by comparing the analytical data with ecological screening levels (ESLs) from the following sources in order of priority: USEPA (2005b) EcoSSLs, USEPA (2003e) Region 5 Ecological Screening Levels, and ORNL values for soil (Efroymson et al. 1997a,b). Table 3-25 presents the selection of surface soil COPECs for the ecological risk assessment. As summarized in Table A.3.ERA-1, 30constituents were identified as COPECs in surface soil as follows:

Three VOCs (1,2,4-trimethylbenzene; m,p-xylene, and xylenes [total]) were detected in surface soil. HQs were less than or equal to 1 for all three constituents, and as a result, no VOCs were identified as COPECs in surface soil.

Two SVOCs (carbazole and dibenzofuran) were detected in surface soil. Neither of these constituents had an ESL and so HQs could not be calculated; as a result, both were identified as COPECs for surface soil.

Four herbicides (2,4-D; dalapon; dicamba; and MCPP) were detected in surface soil. 2,4-D had a calculated HQ of less than or equal to 1; however, ESLs were not available for dalapon, dicamba, and MCPP and so HQs could not be calculated. As a result, these three herbicides were identified as COPECs for surface soil.

Two pesticides (4,4'-DDD and methoxychlor) were detected in surface soil; however, both of these constituents had HQs less than or equal to 1 however they are considered bioaccumulative and were therefore identified as COPECs for surface soil.

Eighteen PAHs were detected in surface soil. Seven of these detected constituents had HQs greater than 1, while the remaining constituents were less than or equal to 1. However, ten of the PAHs with HQs less than 1 are considered bioaccumulative. As a result, all of the detected PAHs except 1-methylnaphthalene were identified as COPECs for surface soil.

Twenty-two inorganics were detected in surface soil. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Fourteen constituents had HQs greater than 1 or were considered bioaccumulative, and two constituents (antimony and iron) did not have an ESL available and so an HQ could not be calculated. However, maximum concentrations of aluminum, chromium, , thallium, and vanadium were all below the background concentrations; as a result, only cobalt, copper, iron,manganese, selenium, and lead were identified as COPECs.

3.5.1.2 Sediment

Sediment COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Sediment Screening Levels; ORNL values (Jones et al. 1997); and USEPA (2008d) Region 5 Ecological Screening Levels for sediment. Table 3-26 presents the selection of sediment COPECs for the ecological risk assessment. As summarized in Table A3.ERA-2, 37constituents were identified as COPECs in sediment as follows:

Six VOCs were detected in sediment. Only two of these constituents (acetone and carbon disulfide) had an HQ greater than 1. As a result, these two constituents were identified as COPCs for sediment.

Two SVOCs (4-methylphenol and di-n-butylphthalate) were detected in sediment; however, both of these constituents had an HQ of less than or equal to 1 and were not identified as COPCs for sediment.

Six pesticides were detected in sediment; all of these constituents had an HQ of less than or equal to 1 but are considered bioacculative and were therefore identified as COPCs for sediment.

Eighteen PAHs were detected in sediment. All but two (naphthalene and 1-methylnapthlane) were either identified as bioccumulative or had an HQ greater than 1 and were identified as COPECs for sediment.

Twenty-one inorganics were detected in sediment. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Nine constituents were either identified as bioaccumulative or had an HQ greater than one, and four constituents (barium; beryllium; thallium; and vanadium) did not have ESLs. There were no background data available for sediments. Consequently, arsenic, barium, beryllium, chromium, copper, iron, lead, manganese, nickel, thallium, vanadium, and zinc were identified as COPECs for sediment.

3.5.1.3 Surface Water

Surface water COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008c) Region 3 Surface Water Screening Levels; ORNL values (Suter and Tsao 1996); USEPA (2003e) Region 5 Ecological Screening Levels; and USEPA (2008e) Ambient Water Quality Criteria for surface water. Table A.3.ERA-3 presents the selection of surface water COPECs for the ecological risk assessment.

Three VOCs were detected in surface water. Only one of these constituents, chloroform, had an HQ greater than 1. In addition, an ESL was not available for bromodichloromethane, and an HQ could not be calculated. As a result, both bromodichloromethane and chloroform were identified as COPECs for surface water.

Three pesticides were detected in surface water. Dieldrin was identified as bioaccumulative and 4,4'-DDT had an HQ greater than 1. As a result, these constituents were identified as COPEC for surface water.

Five PAHs were detected in surface water. All but naphthalene and 2-methylnapthalene were either identified as bioaccumulative or had HQs greater than 1 and were identified as COPECs for surface water.

Fifteen inorganics were detected in surface water. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Of the remaining inorganics, nine were either identified as bioaccumulative or had HQs greater than 1 and therefore considered COPECs for surface water.

3.5.2 Summary of Selected Constituents of Potential Ecological Concern

Thirty constituents were selected as COPECs in surface soil, thirty-seven constituents were selected as COPECs in sediment, and sixteen constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was bioaccumulative or an HQ could not be calculated because an ESL was not available.

3.5.3 Refinement of Risk Calculations for Direct Contact Constituents of Potential Ecological Concern

The list of COPECs identified in the BERA was reevaluated by calculating refined HQs. The refined HQs were calculated for the COPECs identified in the SLERA using refined EPCs. As indicated for the SLERA screen, constituents identified as bioaccumulative were carried forward into food chain models. The results of the recalculation of the HQs for the BDDT are summarized in the subsections below.

3.5.3.1 Surface Soil

Thirty COPECs in surface soil were carried forward into the BERA. When refined EPCs were compared with the ESLs, only eight constituents (benzo[a]anthracene; benzo[a]pyrene; chrysene; naphthalene; cobalt; copper; lead; and manganese) had a refined HQ greater than 1. In addition, ESLs were not available for six other constituents (carbazole; dibenzofuran; dalapon; dicamba; MCPP; and iron). The BERA results for surface soil COPECs at the BDDT are presented in Table A.3.ERA-4 and are discussed below:

<u>Semi-Volatile Organic Compounds</u>: Two SVOCs (carbazole and dibenzofuran) were retained in the BERA because an ESL was not available and so HQs could not be calculated. Due to the relatively low concentrations detected (less than 5 mg/kg), and the physical properties of these two SVOCs (e.g., biodegradation in soil and low potential for bioaccumulation), adverse effects to wildlife due to SVOC exposure are considered unlikely.

<u>Herbicides</u>: Three herbicides (dalapon; dicamba; and MCPP) were retained in the BERA because an ESL was not available and so HQs could not be calculated. These three constituents were detected in the one sample that was analyzed for these herbicides. The concentrations detected were relatively low, and none of the three herbicides were detected in any surface water or sediment samples downgradient of the site. Based on this information, adverse effects to wildlife exposed to herbicides at the site are unlikely.

<u>Polycyclic Aromatic Hydrocarbons</u>: Four PAHs (benzo[a]anthracene; benzo[a]pyrene; chrysene; and naphthalene) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. The ESLs for the four constituents with HQs greater than 1 were obtained from USEPA (2003e) Region 5, and are especially conservative values based on toxicity to the masked shrew. These results are further discussed below.

- Naphthalene was the only PAH not identified as a bioaccumulative COPEC. The HQ calculated using the USEPA (2003e) Region 5 value for this PAH was 70; however, as previously mentioned this Region 5 ESL was based on a conservative food chain model. While alternate toxicologically based ESLs were not available for naphthalene, additional dietary benchmarks were available from Sample et al (1996) for other PAHs. The benchmarks developed by Sample et al (1996) are NOAEL-based dietary benchmarks for mammals exposed to a constituent via ingestion of food. Since naphthalene is not a bioaccumulative COPEC, assuming the naphthalene concentration in all food items is equivalent to the concentration in surface soil provides a conservative estimate of dietary exposure. That is, the receptor would have to have a diet of 100 percent soil to receive the dose associated with the Sample et al (1996) benchmark. The NOAEL benchmark values for benzo(a)pyrene, the most conservative of the PAHs, ranged from 1.98 mg/kg (for short-tailed shrew) to 8.0 mg/kg (for meadow vole) (Sample et al 1996). The EPC for naphthalene, 6.839 mg/kg, is within this range of reported benchmark concentrations. In addition, while the concentrations above the ESL may cause localized impacts to ecological receptors; overall, the total area of concern is within 1 acre and is unlikely to pose a significant adverse ecological impact to ecological receptors at the population-level.

Based on these considerations, adverse effects to wildlife exposed to PAHs at the BDDT are unlikely given the site-specific food chain model results and the similarity of naphthalene concentrations with those below NOAEL-based benchmark values.

Inorganics: Five inorganics (cobalt; copper; iron; manganese; and lead) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1, or an HQ could not be calculated because an ESL was not available. In addition, selenium was retained because it was identified as bioaccumulative. These results are discussed below:

- Cobalt –Only one sample exceeded the background value of 72.3 mg/kg established at the site. Consequently, adverse effects to wildlife exposed to cobalt are unlikely given the similarity of detected concentrations with the site background value.

- Copper –Only three concentrations were above the background value of 53.5 mg/kg established at the site. In addition, as discussed in the sections below, when this COPEC was further evaluated in the site-specific terrestrial food chain model, the calculated HQ values were all less than 1. Based on these considerations, adverse impacts are not expected for wildlife exposed to copper at the BDDT area.

- Iron –One sample was detected above site background. All of the concentrations were within the range of background samples detected at the site. Consequently, adverse effects to wildlife exposed to iron are unlikely given the similarity of detected concentrations with the site background value and range.

- Manganese –Only one concentration was above the background value of 2,543 mg/kg established at the site. Consequently, adverse effects to wildlife exposed to manganese are unlikely given the similarity of detected concentrations with the site background value.

- Lead –Only one concentration was detected outside of the range of background samples detected at the site (2.1 mg/kg to 256 mg/kg). In addition, as discussed in the sections below, when this COPEC was further evaluated in the site-specific terrestrial food chain model, the calculated HQ values were all less than 1. Based on these considerations, adverse impacts are not expected for wildlife exposed to lead at the BDDT area.

- Selenium—The maximum detected concentration of selenium was below the ESL, therefore, it was only retained in the BERA for evaluation in the food chain model. As discussed in the sections below, when this COPEC was further evaluated in the site-specific terrestrial food chain model, the calculated HQ values were all less than 1. Based on these considerations, adverse impacts are not expected for wildlife exposed to selenium at the BDDT area.

In addition to this analysis, twenty COPECs were evaluated in the terrestrial food chain model presented in Section 3.5.4.1.

3.5.3.2 Sediment

Thirty-seven COPECs in sediment were carried forward into the BERA. When refined EPCs were compared with the ESLs, 15 constituents had a refined HQ greater than 1. In addition, ESLs were not available for four other constituents. The BERA results for sediment COPECs at the BDDT are presented in Table A.3.ERA-5 and are discussed below:

Volatile Organic Compounds: Two VOCs (acetone and carbon disulfide) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1 as follows:

Building Debris Disposal Trench Area

Acetone – Acetone was detected in 5 out of 13 sediment samples, with concentrations ranging from 0.022 mg/kg to 0.037 mg/kg. While all of these concentrations were above the ESL of 0.0099 mg/kg, acetone is a common laboratory contaminant and was also detected in the laboratory blank. Consequently, adverse effects to aquatic life exposed to acetone are unlikely given the low concentrations and the uncertainty that the VOC was actually detected in the sediment samples.

Carbon disulfide – Carbon disulfide was detected in 6 out of 13 sediment samples, with concentrations ranging from 0.00099 mg/kg to 0.0015 mg/kg. While all of these concentrations were above the ESL of 0.000851 mg/kg, the HQ calculated was only slightly greater than the benchmark value of 1 (HQ=2). Consequently, adverse effects to aquatic life exposed to carbon disulfide are unlikely given the low detected concentrations.

Polycyclic Aromatic Hydrocarbons: Eleven PAHs were retained in the BERA because the calculated HQs were greater than the benchmark value of 1 as seen in Table A.3.ERA-5. Calculated HQs for these PAHs ranged from 2 to 10. Since PAHs were COPECs in this ERA, the ESBTU approach was used to calculate a total TU which was compared to the target TU benchmark of one (Table A.3.ERA-6). When available,sample specific TOC were used. TOC ranged from 2.2% to 5.4% at the BDDT, with an average of 3.4%. As previously discussed, a default UF of 2.75 was applied to the total TU to obtain an accurate estimation with 50% confidence. The total TU for 16 of the 17 sediment samples taken at the BDDT were below the benchmark of one and the total TU for the other sample was equal to one, indicating that the potential for adverse effects to aquatic life at the BDDT is unlikely. Consequently, adverse effects to aquatic life exposed to PAHs are unlikely.

Inorganics: Six inorganics were retained in the BERA because the calculated HQs were greater than the benchmark value of 1, or an HQ could not be calculated because an ESL was not available. These results are discussed below:

Barium –All but one of these detected concentration were below the soil background value of 209 mg/kg established at the site (sediment background data is unavailable). Consequently, adverse effects to aquatic life exposed to barium are unlikely given the similarity of detected concentrations with the site background value.

Building Debris Disposal Trench Area

Beryllium – Beryllium was detected in 13 out of 13 sediment samples, with concentrations ranging from 0.7 mg/kg to 1.3 mg/kg. While no screening value was available for beryllium and no background sediment data were collected, all of these detected concentrations were within the range of soil background values at the site (0.61 mg/kg to 2.5 mg/kg). Consequently, adverse effects to aquatic life exposed to beryllium are unlikely given the similarity of detected concentrations with the range of site background values.

Iron – Iron was detected in 13 out of 13 sediment samples, with concentrations ranging from 16,400 mg/kg to 56,200 mg/kg. While all but three of these concentrations were above the ESL of 20,000 mg/kg, and no background sediment data was collected, all of these detected concentrations were within the range of soil background values (7,250 mg/kg to 67,700 mg/kg) detected at the site. Consequently, adverse effects to aquatic life exposed to iron are unlikely given the similarity of detected concentrations with the range of site background values.

Manganese – Manganese was detected in 13 out of 13 sediment samples, with concentrations ranging from 387 mg/kg to 3,340 mg/kg. All but one of these concentrations was detected above the ESL of 460 mg/kg. While no background sediment data were collected, all of these detected concentrations were below the soil background value of 2,543 mg/kg established for the site. Consequently, adverse effects to aquatic life exposed to manganese are unlikely given the similarity of detected concentrations with the site background value.

Thallium – Thallium was detected in 9 out of 13 sediment samples, with concentrations ranging from 0.09 mg/kg to 1.1 mg/kg. While no screening value was available for thallium and no background sediment data were collected, all of these detected concentrations were below the soil background value of 2.11 mg/kg established for the site. Consequently, adverse effects to aquatic life exposed to thallium are unlikely given the similarity of detected concentrations with the site background value.

Vanadium – Vanadium was detected in 13 out of 13 sediment samples, with concentrations ranging from 31.6 mg/kg to 75.7 mg/kg. While no screening value was available for vanadium and no background sediment data were collected, all of these detected concentrations were below the established soil background values at the site. Consequently, adverse effects to aquatic life exposed to vanadium are unlikely given the similarity of detected concentrations with the site background value.

In addition to this analysis, twenty-seven COPECs were evaluated in the aquatic food chain model described in Section 3.5.4.2.

3.5.3.3 Surface Water

Sixteen COPECs in surface water were carried forward into the BERA. When refined EPCs were compared with the ESLs, only five constituents had a refined HQ greater than 1. In addition, an ESL was not available for bromodichloromethane. The BERA results for surface water COPECs at the BDDT are presented in Table A.3.ERA-7 and are discussed below:

Volatile Organic Compounds: Bromodichloromethane was detected in only 1 out of 13 surface water samples, at a concentration of 0.023 mg/L. Due to the low frequency of detection and the physical properties of this VOC (e.g., high vapor pressure; low bioaccumulative potential), adverse effects to aquatic life due to VOC exposure are considered unlikely.

Pesticides: One pesticide, 4,4'-DDT, was retained in the BERA because the calculated HQ was greater than the benchmark value of 1 (HQ=10). This constituent was detected in only 1 out of 2 samples that analyzed for pesticides and had an HQ of 0.0002 in the sediment. 4,4'-DDT and dieldrin, which was retained because it is bioaccumulative were further evaluated in the aquatic food chain model, as discussed in Section 3.5.4.2.

Inorganics: Four inorganics (aluminum; barium; copper; and thallium) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. These results are discussed below:

Aluminum – Aluminum was detected in all 13 surface water samples, with concentrations ranging from 0.0498 mg/L to 0.603 mg/L. While six of these samples were greater than the ESL of 0.087 mg/L, the HQ calculated was only slightly greater than the benchmark value of 1 (HQ=4). Furthermore, the ESL used from USEPA (2008c) Region 3 and was based on a water quality criterion protective of salmonids (i.e., coldwater habitat species of fish such as trout and salmon) which is likely overly conservative for the type of warmwater habitat (and associated aquatic species) that is prevalent in this locale. When an alternative screening value of 0.46 mg/L from Sample et al. 1996 was used, an HQ of less than 1 was calculated. This alternative screening value is based on the lowest chronic value of aquatic life, and is considered to be a more representative screening value for aluminum at the BDDT. In addition, aluminum was also detected in the laboratory blank, indicating that the aluminum detected in the surface water may have been a laboratory contaminant. Based on these considerations, adverse effects to aquatic life exposed to aluminum are unlikely.

Barium – Barium was detected in all 13 surface water samples, with concentrations ranging from 0.06 mg/L to 0.0825 mg/L. While all of these samples were greater than the ESL of 0.004 mg/L, the ESL used from USEPA (2008c) Region 3 was based on a secondary chronic value from Suter and Tsao 1996, and was established using an extremely limited dataset. An alternative aquatic screening value of 0.22 mg/L from USEPA (2008c) Region 5 was found, which is considered to be a more representative screening value. When this ESL was used, an HQ of less than 1 was calculated. This alternative screening value is based on the chronic standards for aquatic life, and is a more representative screening value for barium at the BDDT. Based on these considerations, adverse effects to aquatic life exposed to barium are unlikely.

Copper – Copper was detected in all 13 surface water samples, with concentrations ranging from 0.012 mg/L to 0.0348 mg/L. While all of these samples were above the ESL of 0.009 mg/L, the HQ calculated was only slightly above the benchmark value of 1 (HQ=3). In addition, the ESL is based on a default surface water hardness value of 100 mg/L. A site-specific hardness value of 196 mg/L (average at the BDDT area) was used to calculate an ESL of 0.01592 mg/L. When this ESL was used, an HQ of 2 was calculated, which again is only slightly above the benchmark value of 1. Based on these considerations, adverse effects to aquatic life exposed to copper are unlikely.

Thallium – Thallium was detected in 4 out of 13 surface water samples, with concentrations ranging from 0.0023 mg/L to 0.0072 mg/L. While all of these samples were above the ESL of 0.0008 mg/L, the ESL used from USEPA (2008c) Region 3 was based on a Canadian Water Quality value. When an alternative ESL of 0.01 mg/L from USEPA (2003e) Region 5 was used, an HQ of less than 1 was calculated. This alternative screening value is based on a Tier II Michigan water quality value established using a robust set of toxicological data for aquatic life. This value is considered to be a more representative screening value for thallium. Based on these considerations, adverse effects to aquatic life exposed to thallium are unlikely.

In addition to this analysis, eight COPECs in surface water were identified as bioaccumulative (dieldrin; acenaphthene, acenaphthylene; fluorene; lead; nickel; silver; zinc) and were evaluated in the aquatic food chain analysis described in Section 3.5.4.2 along with 4,4'-DDT.

3.5.4 Refinement of Assessment and Measurement Endpoints for Bioaccumulative COPECs

Food chain modeling was conducted at the BDDT in order to evaluate the potential ecological effects of the bioaccumulative COPEC in soil, sediment, and surface water on the receptors identified in Section 2.3. COPECs identified in soil were evaluated in the terrestrial food chain, and COPECs identified in sediment and surface water were evaluated in the aquatic food chain. The results for both the maximum and refined scenarios of these models are discussed below.

3.5.4.1 Terrestrial Food chain Model

As summarized in Tables A.3.ERA-8 through A.3.ERA-11, the refined scenario LOAEL and NOAEL HQs for both the short-tailed shrew and the American robin were less than or equal to 1 for all most COPECs. A few PAHs have NOAEL HQs above 1, however, with the exception of dibenzo(ah)anthracene none has a LOAEL HQ above 1 or a NOAEL HQ above 10. It is important to note that dibenzo(ah)anthracene was only detected in 44% of the samples and the TRVs for this chemical were conservatively extrapolated from acute toxicity values so the risks presented are likely to significantly overestimate actual risks. Based on this assessment, it is concluded that . shrews and robins (or other insectivorous mammals and birds) exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of terrestrial food chain modeling HQs, adverse effects are not expected for wildlife exposed to bioaccumulative COPECs in soil at the BDDT.

3.5.4.2 Aquatic Food chain Model

As presented in Tables A.3.ERA-12 through A.3.ERA-15, the refined scenario LOAEL and NOAEL HQs for both the mink and the great blue heron were less than or equal to 1 for all OPECs identified in sediment and/or surface water with the exception of arsenic, which had a slight exceedance of the NOAEL HQ for the mink. These results indicate that mink and herons (or other piscivorous mammals and birds) exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of aquatic food chain modeling HQs, adverse effects are not expected for wildlife exposed to bioaccumulative COPECs in sediment and/or surface water at the BDDT.

3.5.5 Ecological Risk Summary

Screening-level and baseline risk assessments were completed for the BDDT. After the SLERA, 30 constituents were selected as COPECs in surface soil, 37constituents were selected as COPECs in sediment, and 16 constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was considered bioaccumulative, or an HQ could not be calculated because an ESL was not available. After the BERA, 14 constituents in surface soil, 19 constituents in sediment, and six constituents in surface water were retained because the HQs were greater than 1 or an HQ could not be calculated because an ESL was not available. In addition, food chain modeling was evaluated for all those constituents identified as bioaccumulative.

Tables A.3.ERA-16 and A.3.ERA-17 summarize the constituents in surface soil, sediment, and surface water carried through the BERA and evaluated in the terrestrial and/or aquatic food chain models. As shown in these tables, the majority of constituents evaluated in the terrestrial and aquatic food chain refined scenarios had LOAEL and NOAEL HQs less than or equal to 1. Those that exceeded 1 were below 10 with the exception of the NOAEL HQ associated with dibenzo(a,h)anthracene exposures to shrew. However, as noted previously, that chemical was detected in less than half of the samples analyzed, and the TRVs evaluated were conservatively extrapolated from acute studies, so the risks are likely ovestimated Based on the overall analysis of the ERA for the BDDT, the results indicate that adverse effects are not expected for wildlife at the site.

As discussed in Section 5.1 of the RI, previous site restoration activities mitigated the source area and potential exposure pathways along the trench. Because the soils in the riprap covered portion of the BDDT were not included in the soil dataset for the ERA (as discussed in Section 3.3), the potential impact of this approach was evaluated by comparing the concentrations of constituents in the soils in the riprap covered portion of the BDDT with the concentrations used to develop the EPCs for the ERA.

To do this, the data from the 14 surface soil locations under the riprap (DTSB1, DTSB5, DTSB13, DTSB35, DTSB36, DTSB37, DTSB38, DTSB39, DTSB40, DTSB41, DTSB42, DTSB43, DTSB44, and DTSB45) were evaluated EPCs were calculated for evaluation in the ERA. As shown in Table A.3.ERA-18, all HQs for short-tailed shrew were below 1 with the exception of dibenzo(a,h)anthracene and ideno(1,2,3-cd)pyrene. The HQs were comparable to those calculated for the rest of the BDDT area and are likely due to the conservatism inherent in the PAH TRVs as previously discussed. Based on this analysis, adverse affects to wildlife are not expected to be associated with the rip-rap area.

3.6 BDDT Summary and Conclusions

An HHRA was conducted to evaluate exposure to COPCs in surface soil, combined surface and subsurface soil, sediment, and surface water for site workers, construction workers, hypothetical adult residents, and hypothetical child residents under both current and future land-use conditions. Soils in the entire BDDT area and soils in the rip rap portion of the BDDT were evaluated separately to determine if soils under the rip rap would present a higher risks in the event that they become accessible in the future. The calculated excess lifetime cancer risks and hazards were within the USEPA's target risk range of 1×10^{-6} to 1×10^{-4} or less than or equal to the hazard index of 1,with the exception of the future resident. The ELCR for the resident exceeded 1×10^{-4} mostly due to benzo(a)pyrene. Hazards exceeded 1 for the child resident due to exposure to the maximum concentration of cobalt in subsurface soil, the only sample result for cobalt that exceeded the background range.

Potential exposure to the COPCs during industrial use of the BDDT and riprap portion only resulted in ELCRs and HIs within the target risk range and equal to the hazard benchmark.

The results of the human health risk assessment indicate that residential redevelopment of the BDDT area as a whole or the rip rap portion alone may result in risks or hazards outside the regulatory benchmarks. Exposure to benzo(a)pyrene resulted in risks greater than 1×10^{-4} for the hypothetical future resident. Exposure to cobalt resulted in slightly elevated hazards for child residents. However, the cobalt hazards were driven by a single sample with an elevated concentration. All of the other detections of cobalt at the BDDT were within the background range.

A SLERA and BERA were completed for the BDDT, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial

Building Debris Disposal Trench Area

and aquatic food chain models indicate that adverse effects are not expected for wildlife at the BDDT.

Overall, the results of the HHRA and ERA indicated that potential risks associated with the site are within acceptable ranges for current and future industrial use of the site. However, risks are present under the hypothetical residential land use scenario. The primary risk driver under the residential land use scenario is benzo(a)pyrene. The only non-cancer risk driver for a residential use scenario is cobalt, and that constituent was only detected at a concentration above an applicable screening level in one isolated sample. The elevated cobalt detection is unlikely to be the result of disposal activities at the site and is likely naturally occurring.

4. Bag Loading Area

4.1 Site Description and History

The BLA is located along the southwestern boundary of the RFAAP-NRU, to the south of the RY. The BLA ran two black powder bag loading production lines from 1941-1943. Ten buildings were once present onsite; however, all process equipment, wooden roofs, and wooden walls have been removed from the buildings, leaving only concrete slabs and cinder block walls. The concrete slab floors in Buildings 404 through 413 (including the second story floors of Buildings 404 and 407) were covered in a conductive flooring material that contained various metals and asbestos. This conductive flooring was used to prevent the build-up of static charges in areas where energetic materials were handled. Removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and break away from the underlying concrete. In some cases, the flooring has degraded into a red powder-like material and washed onto the surrounding soils. The concrete walls of these buildings were also painted with lead-based paint. Deterioration of the paint may have provided a potential source of lead to the soils immediately surrounding the former building areas. Buildings 414 through 416 did not contain conductive flooring or concrete walls and are not considered an environmental concern at BLA. Surface water at the BLA generally drains to the unnamed stream located to the north of the BLA via overland flow and through series of drainage ditches/culverts.

4.2 Physical Setting

Topography in the vicinity of the BLA buildings is generally flat. Vegetation is mostly limited to grass and small shrubs. Surface water is drained through a series of drainage ditches and culverts. Surface soil at the BLA consists of tan to dark brown silty clay and clay. The BLA is located on a hilltop and the soil is typical of the Lowell Silt Loam which forms from the weathering of limestone and interbedded shale. The Lowell Silt Loam is found on the hills and ridges throughout the NRU.

4.3 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. Risk assessment datasets for soil, sediment, and surface water for the BLA were prepared then summarized and statistically analyzed. Risk assessment datasets summaries highlighting: the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPC are presented in Tables A.4.Data-1 through A.4.Data-5.

4.4 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with constituents detected in soil, sediment and surface water samples collected at the BLA. The risk assessment approach follows the Radford Army Ammunition Plant Final Master Work Plan (URS 2003). The risk assessment approach is based on Virginia and USEPA guidance for risk assessments (USEPA 2004a; 2000a; 1997a; 1992; 1991a; 1989). This section summarizes the occurrence of constituents in each medium and identifies COPCs at the BLA for the human health risk assessment; identifies the potential human exposure scenarios relevant to the BLA; and presents the estimated human health risks associated with the identified COPCs and the relevant human exposure scenarios at the BLA.

4.4.1 Selection of Constituents of Potential Concern

This section discusses the selection of COPCs for each medium.

4.4.1.1 Surface Soil

Surface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.4.Data-1 summarizes the selection of surface soil COPCs for the HHRA.

Nine VOCs were detected in surface soil. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values with the exception of 3-octanone and d-limonene, which did not have USEPA (2009a) residential soil RSLs. As a result, only 3-octanone and d-limonene were identified as COPCs for surface soil.

Nine SVOCs were detected in surface soil. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values with the exception of carbazole, which did not have a value. As a result, carbazole was identified as a COPC for surface soil.

Seven explosives were detected in surface soil. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSLs with the exception of pentaerythritol tetranitrate, which did not have a value. As a result, only pentaerythritol tetranitrate was identified as a COPC for surface soil.

Nine pesticides were detected in surface soil. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values and were not identified as COPCs in surface soil.

Eighteen PAHs were detected in surface soil. Seven of these detected constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene) were detected at concentrations above the USEPA (2009a) residential soil RSLs and were identified as COPCs for surface soil.

One PCB, Aroclor 1254, was detected in surface soil. This constituent was detected above the USEPA (2009a) residential soil RSL value and was identified as a COPC for surface soil.

Twenty-three inorganics were detected in surface soil. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Eight of these constituents (aluminum; antimony; arsenic; barium; cadmium; cobalt; copper; iron; lead; manganese; mercury; thallium; vanadium; and zinc) were above the USEPA (2009a) residential soil RSL values. However, aluminum, thallium, and vanadium were all detected below the background concentrations. As a result, only antimony, arsenic, barium, cadmium, cobalt, copper, iron, lead, manganese, mercury and zinc were identified as COPCs for surface soil.

Finally, asbestos has also been detected in surface soils around some of the buildings in the BLA in areas where conductive flooring has degraded into a red powder-like material that has washed onto the surrounding soils adjacent to those buildings. Soil sampling and activity-based air sampling have been conducted in selected areas of the BLA and are discussed in Section 6.4.7 of the RI. The results of this sampling indicate that asbestos is also a COPC for surface soil at this site. However, because asbestos is evaluated differently than other chemical COPCs, the evaluation of asbestos is separately discussed in Section 4.4.5 of this HHRA.

4.4.1.2 Combined Surface and Subsurface Soil

Combined surface and subsurface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.4.Data-2 presents the selection of combined surface and subsurface soil COPCs for the HHRA. As summarized in Table A.4.Data-2, 24 constituents were identified as COPCs in combined surface and subsurface soil.

Bag Loading Area

Nine VOCs were detected in combined surface and subsurface soil. All of these constituents were detected at concentrations below their respective USEPA (2009a) residential soil RSLs with the exception of 3-octanone and d-limonene, which didn't have USEPA (2009a) residential soil RSLs. As a result, only 3-octanone and d-limonene were identified as COPCs for combined surface and subsurface soil.

Nine SVOCs were detected in combined surface and subsurface soil. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values with the exception of carbazole, which did not have a value. As a result, only carbazole was identified as a COPC for combined surface and subsurface soil.

Seven explosives were detected in combined surface and subsurface soil. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values with the exception of pentaerythritol tetranitrate, which did not have a value. As a result, only pentaerythritol tetranitrate was identified as a COPC for combined surface and subsurface soil.

Nine pesticides were detected in combined surface and subsurface soil. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values and were not identified as COPCs for combined surface and subsurface soil.

Eighteen PAHs were detected in combined surface and subsurface soil. Seven of these detected constituents were detected at a maximum concentration above the USEPA (2009a) residential soil RSL values and were identified as COPCs for combined surface and subsurface soil.

One PCB, Aroclor 1254, was detected in combined surface and subsurface soil. This constituent was detected at concentrations above the USEPA (2009a) residential soil RSL and was identified as a COPC for combined surface and subsurface soil.

Twenty-three inorganics were detected in combined surface and subsurface soil. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Fourteen of these constituents (aluminum; antimony; arsenic; barium; cadmium; cobalt; copper; iron; lead; manganese; mercury; thallium; vanadium; and zinc) were detected at maximum concentrations above the USEPA (2009a) residential soil RSL values. However, thallium and vanadium were both detected below the background concentrations. As a result, only aluminum, antimony, arsenic, barium, cadmium, cobalt, copper, iron, lead, manganese, mercury and zinc were identified as COPCs for combined surface and subsurface soil.

4.4.1.3 Sediment

Sediment COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.4.Data-3 presents the selection of sediment COPCs for the HHRA. As summarized in Table A.4.Data-3, five constituents were identified as COPCs in sediment.

Two VOCs (acetone and toluene) were detected in sediment. Both of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values and were not identified as COPCs in sediment.

One SVOC, bis(2-ethylhexyl)phthalate, was detected in sediment. This constituent was detected at a maximum concentration below the USEPA (2009a) residential soil RSL value and was not identified as a COPC in sediment.

Seven pesticides (4,4'-DDD; 4,4'-DDE; 4,4'-DDT; beta-BHC; alpha-chlordane; gamma-chlordane; and dieldrin) were detected in sediment; however, all of these constituents were below the USEPA (2009a) residential soil RSL values and were not identified as COPCs in sediment.

Fifteen PAHs (2-methylnaphthalene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in sediment; however, all of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values and were not identified as COPCs in sediment.

Nineteen inorganics (aluminum; antimony; arsenic; barium; beryllium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; nickel; potassium; sodium; thallium; vanadium; and zinc) were detected in sediment. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Five of these constituents (aluminum; arsenic; cobalt; iron; and manganese) were above the USEPA (2009a) residential soil RSL values. Consequently, only aluminum, arsenic, cobalt, iron, and manganese were identified as COPCs for sediment.

4.4.1.4 Surface Water

Surface water COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for tap water. Table A.4.Data-4 presents the selection of surface water COPCs for the HHRA. As summarized in Table A.4.Data-4, six constituents were identified as COPCs.

Two VOCs (carbon disulfide and chloroform) were detected in surface water. Both of these constituents were detected at concentrations below the USEPA (2009a) tap water RSL values and were not identified as COPCs for surface water.

Two SVOCs (butylbenzylphthalate and di-n-buthylphthalate) were detected in surface water; however, both of these constituents were detected at concentrations below the USEPA (2009a) tap water RSL values and were not identified as COPCs for surface water.

One explosive, m-nitrotoluene, was detected in surface water. This constituent was detected at concentrations below the USEPA (2009a) tap water RSL value and was not identified as a COPC for surface water.

One herbicide, 2,4-D, was detected in surface water. This constituent was detected at concentrations below the USEPA (2009a) tap water RSL value and was not identified as a COPC for surface water.

One pesticide, dieldrin, was detected in surface water. This constituent was detected at a maximum concentration above the USEPA (2009a) tap water RSL value and was identified as a COPC for surface water.

Six PAHs (benzo[a]anthracene; benzo[b]fluoranthene; chrysene; fluoranthene; phenanthrene; and pyrene) were detected in surface water. All six of these detected constituents were detected at concentrations below the USEPA (2009a) tap water RSL values and were not identified as COPCs for surface water.

Sixteen inorganics (aluminum; antimony; arsenic; barium; calcium; chromium; copper; iron; lead; magnesium; manganese; mercury; potassium; selenium; sodium; and zinc) were detected in surface water. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Five of these detected constituents (arsenic; copper; lead; manganese; and mercury) were detected above the USEPA (2009a) tap water RSL values. As a result, only arsenic, copper, lead, manganese, and mercury were identified as COPCs for surface water.

4.4.2 Summary of Selected Constituents of Potential Concern

Twenty-three constituents were selected as COPCs in surface soil at the BLA, including two VOCs (3-octanone and d-limonene), one SVOC (carbazole), seven PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene), one PCB (Aroclor 1254), one explosive (pentaerythritol tetranitrate), and eleven inorganics (antimony; arsenic; barium; cadmium; cobalt; copper; iron; lead; manganese; mercury; and zinc).

Twenty-four constituents were selected as COPCs in combined surface and subsurface soil at the BDDT, including two VOCs (3-octanone and d-limonene), one SVOC (carbazole), seven PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene), one PCB (Aroclor 1254), one explosive (pentaerythritol tetranitrate), and twelve inorganics (aluminum; antimony; arsenic; barium; cadmium; cobalt; copper; iron; lead; manganese; mercury; and zinc).

Five inorganics were selected as COPCs in sediment at the BDDT, including aluminum, arsenic, cobalt, iron, and manganese.

Six constituents were selected as COPCs in surface water at the BDDT, including one pesticide (dieldrin), and five inorganics (arsenic; copper; lead; manganese; and mercury).

4.4.3 Determination of Exposure Point Concentrations

Twenty-three constituents were selected as COPCs in surface soil, twenty-four constituents were selected as COPCs in combined surface and subsurface soil, five constituents were selected as COPCs in sediment, and six constituents were selected as COPCs in surface water because the maximum detected concentrations were greater than the corresponding USEPA (2009a) RSL or no RSL was available. The EPCs for these COPCs are summarized in Table A.4.HHRA-5.

4.4.4 Human Health Risk Characterization

The physical and chemical properties and toxicity values used to evaluate excess lifetime cancer risks and non-cancer hazards are presented in Tables A.2-3 through A.2-9. The exposure assumptions used to evaluate potentially exposed receptors are presented in Table A.2-10. The equations used in the risk characterization calculations are presented in Tables A.2-11 through A.2-15.

Exposure to the COPCs in soil, sediment, and surface water were evaluated for direct contact. VOCs identified as COPCs in the BLA were also evaluated for inhalation via vapor migration into buildings. Two VOCs, 3-octanone and d-limonene, were identified as soil COPCs at the BLA. Those two COPCs do not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area.

Results of the risk characterization are discussed below. The ELCRs and non-cancer hazards are summarized in Table A.4.HHRA-16. The blood lead level model estimates for each potentially exposed receptor included in the risk assessment for the BLA are summarized in Table A.4.HHRA-20.

4.4.4.1 Site Worker

A current or future site worker could be present at the BLA area, and could be exposed to surface soil, sediment, or surface water. The ELCR and non-cancer hazard index for site worker exposure to each medium are presented in Tables A.4.HHRA-6 through A.4.HHRA-8. The ELCRs for surface soil, sediment, and surface water are all within or equal to the high end of the USEPA target risk range, and the HIs for each medium are all below the benchmark value of 1.

The total cumulative ELCR for site workers exposed to surface soil, sediment, and surface water at the BLA is 1×10^{-4}, which is equal to the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. This is due to the presence of benzo(a)pyrene in surface soil. The total cumulative HI for site workers is 0.8, which is less than the benchmark of 1.

The 50th percentile blood lead level estimates for the site worker receptor was at 4.9 micrograms per deciliter (µg/dL), below the benchmark of 10 µg/dL; however the 95th percentile fetal blood lead level was at 17 µg/dL which exceeds the benchmark, as seen in Table A.4.HHRA-17.

4.4.4.2 Hypothetical Future Construction Worker

A hypothetical future construction worker could be present at the BLA area, and could be exposed to combined surface and subsurface soil. The ELCR and non-cancer hazard index for hypothetical future construction worker exposure to soil are presented in Table A.4.HHRA-9. The ELCR for combined surface and subsurface soil is within the USEPA target risk range, and the HI is above the benchmark value of 1.

The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the BLA is 7×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 3, which is above the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were above the benchmark of 1 in the gastrointestinal tract due to the presence of copper.

The 50th percentile blood lead level estimates for the construction worker receptor was at 5.2 µg/dL below the target level of 10 µg/dL; however the 95th percentile fetal blood lead levels was calculated to be 18 µg/dL which exceeds the benchmark, as seen in Table A.4.HHRA-19.

4.4.4.3 Hypothetical Future Residents

A hypothetical future adult or child resident could be present at the BLA area, and could be exposed to surface soil, sediment, or surface water. The ELCR and non-cancer hazard index for hypothetical future adult or child resident exposure to each medium are presented in Tables A.4.HHRA-10 through A.4.HHRA-15. The ELCRs for sediment and surface water are both below the USEPA target risk range; however, the ELCR for combined surface and subsurface soil was above the USEPA risk range. The HIs for each medium are below or equal to the benchmark value of 1, with the exception of the child resident exposure to combined surface and subsurface soil.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water at the BLA is 1×10^{-3}, which is greater than the USEPA target risk range of 1×10^{-6} to 1×10^{-4}, primarily due to the presence of benzo(a)pyrene and other PAHs. The total cumulative HI for hypothetical future adult residents is equal to the benchmark of 1. The total cumulative HI for hypothetical future child residents is 12, which is greater than the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were above the benchmark of 1 for the central nervous system, whole body, and immune system, for the gastrointestinal tract, and for the eyes, nails, hair, and skin, due to the presence of Aroclor 1254, copper, and cobalt.

The 50th percentile blood lead level estimates for the hypothetical adult resident receptor was at 6.5 µg/dL which is well below the benchmark of 10 µg/dL; however the 95th percentile fetal blood lead levels was predicted to be 23 µg/dL, which is above the benchmark. The range of blood lead level estimates for the child receptor was 11 µg/dL to 18 µg/dL,, as seen in Table A.4.HHRA-20. The predicted exposure of a child over a seven year period resulted in a geometric mean blood lead concentration of 14.9 µg/dL, also above the 10 µg/dL benchmark, and a prediction of 80 percent of the population having blood lead concentrations above the 10 µg/dL benchmark. Input assumptions to and output for the lead modeling for the child receptor are presented in Table A.4.HHRA-18.

4.4.5 Evaluation of Asbestos

USEPA (2008f) has developed a recommended framework for evaluating asbestos-contaminated sites. That framework states that the measurement of asbestos in soils may not be a good indicator of potential for exposure, due to the fact that the main route of asbestos toxicity is through inhalation of fibers. Thus, the important metric is the measurement of asbestos fibers in air within a breathable zone.

Based on this information, USEPA recommends that activity-based air sampling be conducted in addition to soil sampling, to determine whether disturbance of soils in areas known to contain asbestos can result in the mobilization of asbestos into air where it may be inhaled by the individuals engaged in activities there. Thus the goal of activity-based sampling is to disturb the soil, through an intensive activity such as raking, and then measuring the amount of asbestos that is found in air during that activity.

As discussed in Section 6.4.7 of the RI, ARCADIS conducted an additional investigation in July 2009 to facilitate the evaluation of potential health risks associated with asbestos in soil. This investigation was conducted in accordance with the May 2009 Supplemental Remedial Investigation Work Plan and included the collection of delineation soil samples and the conduct of activity-based air sampling.

Delineation soil samples were collected at select surface soil locations where asbestos had previously been detected or at buildings that lacked historical data. The samples were collected at distances of 1, 5, 10, 15, and 20 ft from buildings and analyzed for asbestos by transmission electron microscopy (TEM) via USEPA method 600/R-

Bag Loading Area

93/116 with sample preparation using California Air Resources Board (CARB) Method 435 and an analytical sensitivity of 0.1% (TEM CARB Level B). This analysis allowed for a quantitative evaluation of asbestos content in soil

To evaluate the risk of exposure to airborne asbestos fibers resulting from asbestos in soil in those areas, ARCADIS also conducted activity-based sampling at two of the BLA buildings (Buildings 404 and 411). This sampling program, which was performed in accordance with USEPA guidance (2008f), included the following:

- Two 10 ft by 10 ft grids were established at Buildings 404 and 411 (total of 4 grids), at 0-10 and 10-20 feet from the building edges, in areas that have had historic asbestos detections.

- Each grid was vigorously raked by a participant wearing Level C personal protection equipment, so that the soil was disturbed. During the raking activity, the participant wore a personal air monitoring pump fitted with a 0.8 µm mixed cellulose ester (MCE) filter and sampling tube mounted in the subjects breathing zone to collect air samples during the raking activity. A stationary air monitoring pump fitted with a 0.8µm filter and sampling tube mounted at a height of 5 feet was also set on the downwind perimeter of the grid to collect air samples during the raking activity. The raking activity was performed for a duration that allowed at least 750 to 1,000 liters of air to be pulled through the filters. The filters from the personal pump and stationary pump were both submitted for laboratory analysis of asbestos by TEM Method 10312.

A complete summary of the samples collected at the BLA during the 2008 and 2009 investigations are included within the historical sampling matrix presented in Table 2-2 of the RI.

To evaluate the results of the air sampling that was conducted, ARCADIS developed risk-based air action levels (AALs) for relevant, site-specific exposure scenarios, using the methodology outlined in USEPA's framework (2008f). These AALs were calculated using the following equation:

$$AAL = \frac{TargetRisk}{\left(IUR_{LTL} * \frac{ET}{CF_1} * \frac{EF}{CF_2}\right)}$$

Where:

AAL = Air action level (fibers/cc)

Target Risk = Target carcinogenic risk level (unitless)
IUR = Inhalation Unit Risk $(f/cc)^{-1}$
ET = Exposure time (hours exposed per day)
CF_1 = Conversion factor (24 hours/day)
EF = Exposure frequency (days exposed per year)
CF_2 = Conversion factor (365 days/year)

As discussed in Section 4.4.4, the exposure scenarios evaluated for the BLA included the current and future site worker, the hypothetical future construction worker, the hypothetical future child resident, and the hypothetical future adult resident. Thus AALs were calculated for these four exposure scenarios, using the exposure frequencies and exposure times, outlined in Table A.2-10, and the inhalation unit risk factors provided in USEPA (2008f; see Table 2) guidance based on the age of first exposure and the duration of exposure provided in Table A.2-10, presented below.

	Current/ Future Site Worker	**Hypothetical Future Construction Worker**	**Hypothetical Future Child Resident**	**Hypothetical Future Adult Resident**
IUR $(f/cc)^{-1}$	0.066	0.0046	0.055	0.075
Start Age	20	20	0	20
Duration	25	1	6	30
ET (hr/day)	8	8	24	24
EF (days/yr)	250	130	350	350

AALs were calculated for each potential receptor group at the 1E-06 and 1E-04 risk levels, representing the lower and upper ends of USEPA's acceptable risk range. The calculated AALs are presented in the following table.

Bag Loading Area

	Calculated AAL (f/cc) at Indicated Target Risk Level	
Receptor Group	**Target Risk = 1E-06**	**Target Risk = 1E-04**
Current/Future Site Worker	0.00007	0.007
Hypothetical Future Construction Worker	0.002	0.2
Hypothetical Future Child Resident	0.00002	0.002
Hypothetical Future Adult Resident	0.00001	0.001

The total asbestos concentration measured in air at Building 404 was non-detect in samples taken from the grid at 10-20 feet from the building edge (BLA404-AA2 and BLA404-AP2). However, asbestos was detected in air samples taken from the grid adjacent to the building (0-10 feet from building edge) (BLA404-AA1 and BLA404-AP1). At BLA404-AA1, the total asbestos structures (specifically chrysotile) measured by Total TEM were 0.022 f/cc[1]; total asbestos structures (i.e., chrysotile) measured at BLA404-AP1 were 0.090 f/cc. The average of all asbestos samples, including the two locations where it was non-detect, was 0.028 g/cc. All of these exceed the AAL of 0.007 f/cc (based on a 1E-04 risk level) calculated for the current and future site worker, as well as the AALs of 0.001 and 0.002 f/cc calculated for the hypothetical future child and adult residents, respectively. None of these exceed the AAL of 0.2 calculated for the hypothetical future construction worker.

The total asbestos concentration measured in air at Building 411 was similar with the total asbestos concentrations nearest the building (BLA411-AA1 and BLA411-AP1) measured to be 0.078 and 0.034 f/cc, respectively. The single concentration measured in the grid located 10-20 feet from the building (BLA411-AP2) was non-detect for asbestos. For all three samples, the average concentration is 0.037 f/cc.

---

[1] Sampling results are reported as structures per cc (s/cc). This is equivalent to fibers per cc (f/cc)

These exceed the calculated AALs for the current/future site worker and the hypothetical future residents, but do not exceed the calculated AAL for the hypothetical future construction worker.

This comparison indicates that the presence of asbestos in the soils closest to Buildings 404 and 411 may result in unacceptable air concentrations if those soils are subject to intensive disturbance. Consequently, they may potentially present a risk to individuals who are engaged in soil-disturbance activities there.

4.4.6 Human Health Risk Summary

Table A.4.HHRA-16 summarizes the calculated cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the BLA. As shown in the table below, the total ELCR values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below or within the benchmark range of 10^{-6} to 10^{-4} for cancer risk, with the exception of hypothetical future residential exposure to combined surface and subsurface soil. The primary contributor to the risk estimates for hypothetical residents is benzo(a)pyrene.

Summary of Calculated ELCRs and HIs for Receptor Exposure Scenarios

RECEPTOR/ EXPOSURE MEDIUM - SCENARIO	ELCR	HI
Site Worker		
Surface Soil - Direct Contact	1E-04	0.7
Sediment – Wading	4E-07	0.007
Surface Water – Wading	2E-06	0.05
TOTAL SITE RISKS (Site Worker):	**1E-04**	**0.8**
Hypothetical Future Construction Worker		
Combined Surface and Subsurface Soil - Direct Contact	7E-06	3
TOTAL SITE RISKS (Construction Worker):	**7E-06**	**3**
Hypothetical Future Adult Resident		
Combined Surface and Subsurface Soil - Direct Contact	-	1
Sediment – Wading	-	0.01
Surface Water – Wading	-	0.01
TOTAL SITE RISKS (Adult Resident):	**-**	**1**
Hypothetical Future Child Resident		
Combined Surface and Subsurface Soil - Direct Contact	-	12
Sediment – Wading	-	0.09
Surface Water – Wading	-	0.04
TOTAL SITE RISKS (Child Resident):	**-**	**12**

Hypothetical Future Aggregate Resident (Adult and Child)		
Combined Surface and Subsurface Soil - Direct Contact	1E-03	-
Sediment – Wading	1E-06	-
Surface Water – Wading	1E-06	-
TOTAL SITE RISKS (Aggregate Resident):	**1E-03**	**-**

The total HI values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are at or below the benchmark of 1 for non-cancer hazard, with the exception of hypothetical future construction worker and hypothetical future child resident exposure to combined surface and subsurface soil. When the HIs are segregated into target site and critical effects, hazards were only greater than the benchmark of 1 in the gastrointestinal (GI) tract for the hypothetical future construction worker, due to copper. For the hypothetical future child resident exposure to surface soil, hazards exceed the benchmark of 1 for the GI tract, due to copper; the eyes, nails hair and skin, due to cobalt and Aroclor 1254; and the immune system, due to Aroclor 1254.

The results of the risk assessment indicated that under industrial exposure scenarios, exposure to lead may pose an unacceptable risk. The predicted blood lead levels for the worker were below the benchmark, but for an unborn fetus were above the benchmark. While there were some samples of lead with concentrations below the screening levels, many of the surface soil concentrations were above the RSL of 750 mg/kg.

Summary of Estimated Blood Lead Levels for Receptor Exposure Scenarios

RECEPTOR	Estimated Blood Lead Level (µg/dL)		
	Adult	Child	Fetus
	50th percentile	Range	95th percentile
SOIL AND SEDIMENT			
Site Worker	4.9	–	17
Hypothetical Future Child	–	11-18	–
Hypothetical Future Adult	6.5	–	23
SOIL			
Hypothetical Future Construction Worker	5.2	–	18

The results of the risks assessment for hypothetical future residential receptors also indicated that lead was a constituent of concern for both adult and child residents. Additionally, benzo(a)pyrene, Aroclor 1254, cobalt and copper were the primary risk and hazard drivers.

As discussed in Section 4.1, removal of the walls and roofs of the buildings has exposed the conductive flooring to weather, causing it to degrade and wash onto the surrounding soils. Based on a comparison of measured asbestos levels in air following intensive activity-based sampling with AALs developed in Section 4.4.5, it appears that asbestos in soils could present risks to current and future site workers or hypothetical future residents.

4.5 Ecological Risk Assessment

The purpose of the ERA is to evaluate whether ecological receptors may be adversely impacted by exposure to site-related constituents detected in surface soil, sediment, and surface water at the BLA. The ERA approach is based on the Master Work Plan (URS 2003) in compliance with CERCLA/SARA and pursuant to RCRA Corrective Action requirements. The ERA was conducted in a manner consistent with Virginia policy and USEPA guidance for ecological risk assessment (USEPA 2001a; 2000b; 1997c). This ERA is intended to provide input for risk management decision-making for the BLA, while maintaining a conservative approach protective of wildlife populations and communities. In accordance with USEPA guidance, the ERA for the BLA commenced with a SLERA and then concluded with a BERA (USEPA 1997c).

This section summarizes the occurrence of constituents in each medium and identifies COPECs at the BLA for the ecological risk assessment; identifies the potential ecological exposure scenarios relevant to the BLA; and presents the estimated ecological risks associated with the identified COPECs and the relevant ecological exposure scenarios at the BLA. Methodologies for data summary and selection of COPECs, exposure assessment, and toxicity assessment for the ERA were presented in Section 2.3.

4.5.1 Selection of Constituents of Potential Ecological Concern

This section discusses the selection of COPECs for each medium. Risks to ecological receptors are calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the hazard quotient (HQ), is a highly conservative surrogate for the assessment endpoints identified in Section 2.3. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse ecological effects are unlikely (USEPA 1997c). HQs greater than 1 indicate that further evaluation is warranted. Therefore, the constituents with HQs greater than 1 are carried forward as COPECs into the BERA. Because the majority of the ESLs measure direct exposures and do not take into account exposures to upper trophic level species, chemicals identified as bioaccumulative were also carried forward as COPECs regardless of whether or not the associated HQ was greater than 1. Finally, as previously described, concentrations of inorganic constituents in soil were compared to soil background concentrations; those with concentrations below background were not considered as COPEC. The COPEC selection process for the BLA area are summarized in the subsections below.

4.5.1.1 Surface Soil

Surface soil COPECs were selected by comparing the analytical data with USEPA (2005b) EcoSSLs, USEPA (2003e) Region 5 ESLs, and ORNL values (Efroymson et al. 1997a,b) for surface soil. Table A.4.ERA-1 presents the selection of surface soil COPECs for the ERA. Fifty-three constituents were identified as COPECs in surface soil.

Nine VOCs (2-butanone; 3-octanone; 4-methyl-2-pentanone; acetone; carbon disulfide; d-limonene; methylene chloride; tetrachloroethene; and toluene) were detected in surface soil. With the exception of 3-octanone and d-limonene, all of these constituents had HQs less than or equal to 1. Neither octanone nor d-limonene had an ESL available and so an HQ could not be calculated. As a result, both 3-octanone and d-limonene were identified as COPECs for surface soil.

Nine SVOCs (2,4-dinitrotoluene; 2,6-dinitrotoluene; benzoic acid; bis[2-ethylhexyl]phthalate; carbazole; dibenzofuran; di-n-butylphthalate; n-nitrosodiphenylamine; and phenol) were detected in surface soil. Four of these constituents (2,4-dinitrotoluene; 2,6-dinitrotoluene; di-n-butylphthalate; and n-nitrosodiphenylamine) had an HQ greater than 1, and three constituents (benzoic acid; carbazole; and dibenzofuran) did not have an ESL so an HQ could not be calculated. As a result, 2,4-dinitrotoluene,2,6-dinitrotoluene, benzoic acid, carbazole, dibenzofuran, di-n-butylphthalate, and n-nitrosodiphenylamine were identified as COPECs for surface soil.

Seven explosives (1,3,5-trinitrobenzene; 1,4-dinitrobenzene; 2,4,6-trinitrotoluene; 4-amino-2,6-dinitrotoluene; m-nitrotoluene; nitroglycerine; and pentaerythritol tetranitrate) were detected in surface soil. ESLs were not available for 2,4,6-trinitrotoluene, m-nitrotoluene, nitroglycerine, and pentaerythritol tetranitrate. As a result these chemicals were all identified as COPECs for surface soil.

Nine pesticides (4,4'-DDD; 4,4'-DDE; beta-BHC; alpha-chlordane; gamma-chlordane; endosulfan I; endrin; heptachlor epoxide; and methoxyclor) were detected in surface soil. Two of these constituents (4,4'-DDD and methoxychlor) had an HQ greater than

1. In addition, an ESL was not available for endosulfan and 4,4'-DDE, beta-BHC, alpha-chlordane, endrin, and heptachlor epoxide were all identified as bioaccumulative. As a result, 4,4'-DDD, 4,4'-DDE, endosulfan, methoxychlor, beta-BHC, alpha-chlordane, endrin, and heptachlor epoxide were identified as COPECs in surface soil.

Eighteen PAHs (1-methylnaphthalene; 2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in surface soil. Five of these constituents (benzo[a]anthracene; benzo[a]pyrene; chrysene; naphthalene; and phenanthrene) had an HQ greater than 1 and an additional eleven were identified as bioaccumulative. As a result, all of the detected PAHs except 1-methylnapthalene and 2-methylnapthalene were identified as COPECs for surface soil.

One PCB, Aroclor 1254, was detected in surface soil. This constituent did not have an ESL and so an HQ could not be calculated. Based on that, and the fact that it was identified as bioaccumulative, Aroclor 1254 was identified as a COPEC for surface soil.

Twenty-three inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; silver; sodium; thallium; vanadium; and zinc) were detected in surface soil. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Sixteen of these constituents (aluminum, antimony; arsenic; barium; cadmium; chromium; cobalt; copper; lead; manganese; mercury; nickel; selenium; thallium; vanadium; and zinc) had HQs greater than 1, and one (iron) did not have an ESL available and so an HQ could not be calculated. In addition, silver was identified as bioaccumulative. However, three constituents (aluminum; thallium; and vanadium) had maximum concentrations below the background concentrations. As a result, antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, silver, and zinc were identified as COPECs for surface soil.

Finally, asbestos has also been detected in surface soils around some of the buildings in the BLA in areas where conductive flooring has degraded into a red powder-like material that has washed onto the surrounding soils adjacent to those buildings. Soil sampling and activity-based air sampling have been conducted in selected areas of the BLA and are discussed in Section6.4.7 of the RI. The results of this sampling indicate that asbestos is also a COPC for surface soil at this site.

4.5.1.2 Sediment

Sediment COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Sediment Screening Levels; ORNL values (Jones et al. 1997); and USEPA (2003e) Region 5 Ecological Screening Levels for sediment. Table A.4.ERA-2 presents the selection of sediment COPECs for the ERA. Thirty constituents were identified as COPECs in sediment.

Two VOCs (acetone and toluene) were detected in sediment. Only acetone had an HQ greater than 1, and as a result, was identified as a COPEC in sediment. One SVOC, bis(2-ethylhexyl)phthalate, was detected in sediment; however, this constituent had an HQ less than or equal to 1 and was not identified as a COPEC in sediment.

Seven pesticides (4,4'-DDD; 4,4'-DDE; 4,4'-DDT; beta-BHC; alpha-chlordane; gamma-chlordane; and dieldrin) were detected in sediment. All of these constituents had HQs less than or equal to 1, however, six (4,4'-DDD; 4,4'-DDE; 4,4'-DDT; beta-BHC; alpha-chlordane; and dieldrin) were identified as bioaccumulative and were therefore identified as COPECs in sediment.

Fifteen PAHs (2-methylnaphthalene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in sediment. All had HQs less than 1, however, all were identified as bioaccumulative except 2-methylnapthalene and naphthalene and were therefore dentified as COPECs in sediment.

Nineteen inorganics (aluminum; antimony; arsenic; barium; beryllium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; nickel; potassium; sodium; thallium; vanadium; and zinc) were detected in sediment. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Four constituents (barium; beryllium; thallium; and vanadium) did not have ESLs. Six constituents (arsenic; chromium; copper; lead; nickel; and zinc) were identified as bioaccumulative. Based on this assessment, barium, beryllium, thallium, vanadium, arsenic, chromium, copper, lead, nickel, and zinc were identified as COPECs for sediment.

4.5.1.3 Surface Water

Surface water COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Surface Water Screening Levels; ORNL values (Suter and Tsao 1996); USEPA (2003e) Region 5 Ecological Screening Levels; and USEPA (2008e) Ambient Water Quality Criteria for surface water. Table A.4.ERA-3 presents the selection of surface water COPECs for the ERA. Eighteen constituents were identified as COPECs in surface water as follows:

Two VOCs (carbon disulfide and chloroform) were detected in surface water; however, both of these constituents had an HQ of less than or equal to 1 and were not identified as COPECs for surface water.

Two SVOCs (butylbenzylphthalate and di-n-buthylphthalate) were detected in surface water; however, both of these constituents had an HQ of less than or equal to 1 and were not identified as COPECs for surface water.

One explosive, m-nitrotoluene, was detected in surface water; however, this constituent had an HQ of less than or equal to 1 and was not identified as a COPEC for surface water.

One herbicide, 2,4-D, was detected in surface water; however, this constituent had an HQ of less than or equal to 1 and was not identified as a COPEC for surface water.

One pesticide, dieldrin, was detected in surface water. This constituent had an HQ of less than or equal to 1, however, it is considered bioaccumulative and was therefore identified as a COPEC for surface water.

Six PAHs (benzo[a]anthracene; benzo[b]fluoranthene; chrysene; fluoranthene; phenanthrene; and pyrene) were detected in surface water. Only two of these detected constituents (fluoranthene and pyrene) had an HQ greater than 1, however, the other four were identified as bioaccumulative, therefore all six were identified as COPECs for surface water.

Sixteen inorganics (aluminum; antimony; arsenic; barium; calcium; chromium; copper; iron; lead; magnesium; manganese; mercury; potassium; selenium; sodium; and zinc) were detected in surface water. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Eight of these constituents (aluminum; arsenic; barium; copper; iron; lead; manganese; and mercury) had an HQ greater than 1. An additional three (chromium; selenium; and zinc) were identified as bioaccumulative. Therefore, aluminum, arsenic, barium, chromium, copper, iron, lead, manganese, mercury, selenium, and zinc were identified as COPECs for surface water.

4.5.2 Summary of Selected Constituents of Potential Ecological Concern

Fifty-three constituents were selected as COPECs in surface soil, thirty constituents were selected as COPECs in sediment, and eighteen constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was identified as bioaccumulative, or an HQ couldn't be calculated because an ESL was not available.

4.5.3 Refinement of Risk Calculations for Direct Contact COPECs

The list of COPECs identified in the BERA was reevaluated by calculating refined HQs. The refined HQs were calculated for the COPECs identified in the SLERA using refined EPCs. Constituents identified as COPECs in the BERA that were bioaccumulative were carried forward into food chain models. The results of the recalculation of the HQs for the BDDT are summarized in the subsections below.

4.5.3.1 Surface Soil

Fifty-three COPECs in surface soil were carried forward into the BERA. When refined EPCs were compared with the ESLs, 20 constituents (2,6-dinitrotoluene; di-n-butylphthalate; n-nitrosodiphenylamine; 4,4'-DDD; methoxychlor; benzo[a]anthracene; benzo[a]pyrene; chrysene; naphthalene; antimony; barium; cadmium; chromium; cobalt; copper; lead; mercury; selenium; and zinc) had a refined HQ greater than 1. In addition, ESLs were not available for 12 other constituents (3-octanone; d-limonene; benzoic acid; carbazole; dibenzofuran; 2,4,6-trinitrotoluene; m-nitrotoluene; nitroglycerine; pentaerythritol tetranitrate; endosulfan; Aroclor 1254; and iron). The BERA results for surface soil COPECs at the BLA are presented in Table A.4.ERA-4 and are discussed below:

> <u>Volatile Organic Compounds</u>: Two VOCs (3-octanone and d-limonene) were retained in the BERA because an ESL was not available and so HQs could not be calculated. These VOCs were each detected at very low concentrations (i.e., < 1 mg/kg) in one sample. Based on the low detected concentrations, adverse effects to wildlife due to potential VOC exposure are considered unlikely.

Semi-Volatile Organic Compounds: Seven SVOCs (2,4-dinitrotoluene, 2,6-dinitrotoluene; benzoic acid; carbazole; dibenzofuran; di-n-butylphthalate; and n-nitrosodiphenylamine) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1 or because an ESL was not available and so HQs could not be calculated. These results are discussed below:

2,4-Dinitrotoluene – 2,4-Dinitrotouene was detected in only 9 of the 20 surface samples. Only one of the detected concentrations exceeded the ESL, therefore, adverse effects to wildlife exposed to 2,4-dinitrotoluene are unlikely given the low frequency of detection and low detected concentrations.

2,6-Dinitrotoluene – 2,6-Dinitrotoluene was detected in 3 out of 20 surface soil samples, with concentrations ranging from 0.07mg/kg to 1.9 mg/kg. While all three concentrations were above the ESL of 0.0328 mg/kg, adverse effects to wildlife exposed to 2,6-dinitrotoluene are unlikely given the low frequency of detection and low detected concentrations.

Benzoic acid – Benzoic acid was detected in 4 out of 15 surface soil samples, with concentrations ranging from 0.14 mg/kg to 0.3 mg/kg. While no ESL was available for this SVOC and no HQ could be calculated, it is unlikely that benzoic acid would cause adverse effects to wildlife due to the low frequency of detection and low detected concentrations.

Carbazole – Carbazole was detected in 10 out of 14 surface soil samples, with concentrations ranging from 0.045 mg/kg to 13 mg/kg. While no ESL was available for this SVOC and no HQ could be calculated, it is unlikely that carbazole would cause adverse effects to wildlife due to the physical properties of this constituent (e.g., biodegradation in soil).

Dibenzofuran – Dibenzofuran was detected in 9 out of 14 surface soil samples, with concentrations ranging from 0.016 mg/kg to 2.8 mg/kg. While no ESL was available for this SVOC and no HQ could be calculated, it is unlikely that dibenzofuran would cause adverse effects to wildlife due to the physical properties of this constituent (e.g., biodegradation in soil).

Di-n-butylphthalate – Di-n-butylphthalate was detected in 6 out of 14 surface soil samples, with concentrations ranging from 0.061 mg/kg to 120 mg/kg. While five of these concentrations were above the ESL of 0.15 mg/kg, given the physical properties of this constituent, it is unlikely that di-n-butylphthalate would cause adverse effects to wildlife.

Bag Loading Area

n-Nitrosodiphenylamine – n-Nitrosodiphenylamine was detected in 2 out of 13 surface soil samples, with concentrations ranging from 0.1 mg/kg to 8.3 mg/kg. Only one of these concentrations was above the ESL of 0.545 mg/kg. As a result, it is unlikely that n-nitrosodiphenylamine would cause adverse effects to wildlife due the low frequency of detection and to the physical properties of this constituent (e.g., biodegradation in soil).

Explosives: Four explosives (2,4,6-trinitrotoluene; m-nitrotoluene; nitroglycerine; pentaerythritol tetranitrate) were retained in the BERA because an ESL was not available and so HQs could not be calculated. These constituents were each detected in only 1 out of 16 samples, and at relatively low concentrations. Consequently, adverse effects to wildlife potentially exposed to explosives in soil are unlikely due to their limited occurrence and relatively low concentrations.

Pesticides: Three pesticides (4,4'-DDD; endosulfan; and methoxychlor) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1 or because an ESL was not available and so HQs could not be calculated. An ESL was not available for endosulfan and as a result, an HQ could not be calculated; however, this constituent was detected in only 1 out of 5 samples and at a low concentration. 4,4'-DDD and methoxyclor both had a calculated HQ slightly above the benchmark value of 1 (HQ=2 and HQ=3, respectively). Consequently, adverse effects to wildlife potentially exposed to pesticides are unlikely due to the low frequency of detection and/or the relatively low detected concentrations. In addition, when these COPECs were further evaluated in the site-specific terrestrial food chain model, along with the five additional pesticides identified as being bioaccumulative, all had HQs below the benchmark of 1.

Polycyclic Aromatic Hydrocarbons: Four PAHs (benzo[a]anthracene; benzo[a]pyrene; chrysene; and naphthalene) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. Calculated HQs for these PAHs ranged from 2 to 10. The ESLs for these constituents were obtained from USEPA (2003e) Region 5, and are especially conservative values based on toxicity to the masked shrew.

Naphthalene was the only PAH not identified as a bioaccumulative COPEC. The HQ calculated using the USEPA (2003e) Region 5 value for this PAH was 2, which is only slightly above the benchmark of 1. While alternate ESLs were not available for naphthalene, additional toxicologically-based benchmarks were available from Sample et al (1996) for other PAHs. The benchmarks developed by Sample et al

(1996) are NOAEL-based dietary benchmarks for mammals exposed to a constituent via ingestion of food. Since naphthalene is not a bioaccumulative COPEC, assuming the naphthalene concentration in all food items is equivalent to the concentration in surface soil provides a conservative estimate of dietary exposure. That is, the receptor would have to have a diet of 100 percent soil to receive the dose associated with the Sample et al (1996) benchmark. The NOAEL benchmark values for benzo(a)pyrene, the most conservative of the PAHs, ranged from 1.98 mg/kg to 8.0 mg/kg. The EPC for naphthalene, 0.194 mg/kg, was below this range of acceptable concentrations.

As indicated in Section 4.5.4, with the exception of the dibenzo(a,h)anthracene NOAEL for the shrew, all terrestrial HQs were below 10. It is important to note that the TRVs for this chemical are based on conservative extrapolations from acute toxicity tests and are therefore likely to overestimate risks. Emphasizing the conservative nature of the TRVs, the ESL selected for evaluation of dibenzo(a,h)anthracene in this assessment is actually based on exposures to the masked shrew, and the maximum detected concentration is well below. Consequently, adverse effects to wildlife exposed to PAHs at the site are unlikely given the site-specific food chain model results and the similarity of naphthalene concentrations with those below NOAEL-based benchmark values.

<u>Polychlorinated Biphenyls</u>: One PCB, Aroclor 1254, was retained in the BERA because an ESL was not available from Region 3 or Region 5, and so an HQ could not be calculated. Aroclor 1254 was detected in 9 out of 17 surface soil samples with concentrations ranging from 0.0066 mg/kg to 8.3 mg/kg.

While there are no Aroclor-specific ESLs from Region 5, Region 5 does provide an ESL of 0.000332 mg/kg for PCBs as a group. The maximum and UCL Aroclor 1254 concentrations at the BLA are above this ESL; however, site-specific food chain modeling for the short-tailed shrew and American robin (Section 4.7.4), using conservative exposure assumptions, indicates that the potential risk from exposure to Aroclor 1254 at the BLA is very low. Based on these considerations, adverse impacts are not expected for populations of ecological receptors exposed to Aroclor 1254 at the BLA.

<u>Inorganics</u>: Twelve inorganics (antimony; barium; cadmium; chromium; cobalt; copper; iron; lead; manganese; mercury; selenium; and zinc) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1, or an HQ could not be calculated because an ESL was not available. These results are discussed below:

Bag Loading Area

Antimony – Antimony was detected in 17 out of 38 surface soil samples, with concentrations ranging from 0.2 mg/kg to 8.1 mg/kg. Nine of these concentrations were above the ESL of 0.27 mg/kg. While site-specific background values for antimony were not available, these detected concentrations were compared to the mean soil inorganic background concentrations of 1.2 mg/kg reported for Virginia (USEPA 2003f). The EPC for antimony at the BLA was 1.2 mg/kg, which was equal to the reported background soil concentration for antimony in Virginia. Consequently, adverse effects to wildlife exposed to antimony are unlikely given the similarity of detected concentrations with the state background soil value.

Barium – Barium, like most of the inorganics, occurs naturally at the RFAAP-NRU. However, barium is also one of the known components of the conductive flooring material used in the BLA and IAA buildings. Barium was detected in 40 out of 40 surface soil samples, with concentrations ranging from 45.4 mg/kg to 11,100 mg/kg, with an EPC of 6,101 mg/kg. Sixteen concentrations were greater than the ESL of 330 mg/kg, and nineteen concentrations were above the background value of 209 mg/kg established at the site.

Although there are some soil samples at the BLA with elevated concentrations of barium, a closer examination of the location of those samples in relation to the concrete building foundations, and their spatial extent indicates that the concentrations of barium (and other metals) in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (i.e., in general, concentrations decrease with distance from the foundations; Figure 4-1). For example, in sample location BLA-SS009 (collected 1-foot from the building foundation) the concentration of barium is 1,550 mg/kg; in comparison, the concentration of barium is 115 mg/kg in sample location BLA-SS010 (collected approximately 10 feet away from the foundation), below the background value of 209 mg/kg established at the site. This trend is repeated in other sample locations (i.e., BLA-SS016, which is located within 1 foot of the foundation, versus BLASS10). The areal extent of the affected soils that are around the perimeter of the 7 buildings with conductive flooring at the BLA encompass an area of 40,245 ft^2. When the area of the foundations (17,875 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 16,850 ft^2, or approximately 0.4 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to barium at the BLA.

Cadmium – Cadmium was detected in 30 out of 35 surface soil samples, with concentrations ranging from 0.09 mg/kg to 44.8 mg/kg. Twenty-four concentrations were above the ESL of 0.36 mg/kg, and twenty-three concentrations were above the background value of 0.69 mg/kg established at the site. As previously discussed, a closer examination of the location of those soil samples with elevated levels of cadmium indicates that the concentrations of cadmium in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (Figure 4-1). For example, in sample location BLA-SS009 (located 1 foot from the building foundation) the concentration of cadmium is 5.6 mg/kg, compared to 1.5 mg/kg in sample location BLA-SS11 (located approximately 15 feet away from the foundation), which is within the detected range of background values (0.62 mg/kg to 2.5 mg/kg) at the site. This trend is repeated in other sample locations (i.e., BLA-SS016, which is located within 1 foot of the foundation, versus BLASS10, which is approximately 10 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 7 buildings at the BLA encompass an area of 40,245 ft^2. When the area of the foundations (17,875 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 16,850 ft^2, or approximately 0.4 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to cadmium at the BLA. Additionally, cadmium was further evaluated in the terrestrial food chain model.

Chromium – Chromium was detected in 40 out of 40 surface soil samples, with concentrations ranging from 11.2 mg/kg to 106 mg/kg. While all but one concentration was above the ESL of 26 mg/kg, only five concentrations were above the background value of 65.3 mg/kg established at the site. When the EPC was calculated, this value was below the background value. In addition, the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). Consequently, adverse effects to wildlife exposed to chromium are unlikely given the similarity of detected concentrations with the site background values and the low calculated HQ.

Cobalt – Cobalt was detected in 37 out of 40 surface soil samples, with concentrations ranging from 3.9 mg/kg to 149 mg/kg. While twenty-seven concentrations were above the ESL of 13 mg/kg, only one concentration was above the range of background samples (5.9 mg/kg to 130 mg/kg) detected at the site. In addition, the calculated HQ was only slightly above the benchmark value of 1 (HQ=3). Consequently, adverse effects to wildlife exposed to cobalt are unlikely given the similarity of detected concentrations with the site background values and the low calculated HQ.

Copper – Copper was detected in 40 out of 40 surface soil samples, with concentrations ranging from 23.5 mg/kg to 72,000 mg/kg. Thirty-six concentrations were above the ESL of 28 mg/kg, and twenty-nine concentrations were above the background value of 53.5 mg/kg established at the site. As previously discussed, a closer examination of the location of those soil samples with elevated levels of copper indicates that the concentrations of copper in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (Figure 4-1). For example, in sample location BLA-SS009 (located 1 foot from the building foundation) the concentration of copper is 3,890 mg/kg, compared to 53.4 mg/kg in sample location BLA-SS11 (located approximately 15 feet away from the foundation), which is below the soil background value of 53.5 mg/kg established at the site. This trend is repeated in other sample locations (i.e., BLA-SS016, which is located within 1 foot of the foundation, versus BLASS10, which is approximately 10 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 7 buildings at the BLA encompass an area of 40,245 ft^2. When the area of the foundations (17,875 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 16,850 ft^2, or approximately 0.4 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to copper at the BLA. Additionally, copper was further evaluated in the terrestrial food chain model.

Iron – Iron was detected in 40 out of 40 sediment samples, with concentrations ranging from 8,500 mg/kg to 61,500 mg/kg. While no ESL was available for iron, all but one of these concentrations were below the background value of 50,962 mg/kg established for the site, and all of the concentrations were within the range of background samples detected at the site. Consequently, adverse effects to wildlife exposed to iron are unlikely given the similarity of detected concentrations with the site background value and range.

Lead – Lead was detected in 40 out of 40 surface soil samples, with concentrations ranging from 14.7 mg/kg to 58,000 mg/kg. While all of these concentrations were above the ESL of 11 mg/kg, and 32 concentrations were above the established background value, only 16 concentrations were detected outside of the range of background samples (2.1 mg/kg to 256 mg/kg) detected at the site. As previously discussed, a closer examination of the location of those soil samples with elevated levels of lead indicates that the concentrations of lead in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (Figure 4-1). For example, in sample location BLA-SS009 (located 1 foot from the building foundation) the concentration of lead is 1,830 mg/kg, compared to 143 mg/kg in sample location BLA-SS11 (located approximately 15 feet away from the foundation), which is within the detected range of background values (2.1 mg/kg to 256 mg/kg) at the site. This trend is repeated in other sample locations (i.e., BLA-SS016, which is located within 1 foot of the foundation, versus BLA-SS10, which is approximately 10 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 7 buildings at the BLA encompass an area of 40,245 ft^2. When the area of the foundations (17,875 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 16,850 ft^2, or approximately 0.4 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to lead at the BLA. Additionally, lead was further evaluated in the terrestrial food chain model.

<u>Manganese –</u> Manganese was detected in all of the surface soil samples (i.e., 47) at concentrations ranging from 71 to 3,080 mg/kg. While many of the samples have concentrations exceeding the ESL of 220 mg/kg, only one sample exceeds the background concentration of 2,543 mg/kg. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to manganese at the BLA.

<u>Mercury</u> – Mercury was detected in 33 out of 35 surface soil samples, with concentrations ranging from 0.02 mg/kg to 16.8 mg/kg. Seventeen concentrations were above the ESL of 0.1 mg/kg and the background value of 0.13 mg/kg established for the site. As previously discussed, a closer examination of the location of those soil samples with elevated levels of mercury indicates that the concentrations of mercury in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (Figure 4-1). For example, in sample location BLA-SS009 (located 1 foot from the building foundation) the concentration of mercury is 16.8 mg/kg, compared to 0.14 mg/kg in sample location BLA-SS11 (located approximately 15 feet away from the foundation), which is within the detected range of background values (0.038 mg/kg to 1.2 mg/kg) at the site. This trend is repeated in other sample locations (i.e., BLA-

SS016, which is located within 1 foot of the foundation, versus BLASS10, which is approximately 10 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 7 buildings at the BLA encompass an area of 40,245 ft^2. When the area of the foundations (17,875 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 16,850 ft^2, or approximately 0.4 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to mercury at the BLA.

<u>Selenium</u> – Selenium was detected in 8 out of 39 surface soil samples, with concentrations ranging from 0.39 mg/kg to 1.9 mg/kg. While five concentrations were above the ESL of 0.52 mg/kg, the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). Consequently, adverse effects to wildlife exposed to selenium are unlikely given the low calculated HQ. This COPEC was further evaluated in the terrestrial food chain model.

<u>Zinc</u> – Zinc was detected in 40 out of 40 surface soil samples, with concentrations ranging from 37.2 mg/kg to 12,500 mg/kg. Twenty-nine concentrations were greater than the ESL of 46 mg/kg, and twenty-one concentrations were above the background value of 202 mg/kg established at the site. As previously discussed, a closer examination of the location of those soil samples with elevated levels of zinc indicates that the concentrations of zinc in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (Figure 4-1). For example, in sample location BLA-SS009 (located approximately 1 foot from the foundation of the building) the concentration of zinc is 2,600 mg/kg, compared to 164 mg/kg in sample location BLA-SS11 (located approximately 15 feet away from the foundation), which is below the background value of 202 mg/kg established at the site. This trend is repeated in other sample locations (i.e., BLA-SS016, which is located within 1 foot of the foundation, versus BLASS10, which is approximately 10 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 7 buildings at the BLA encompass an area of 40,245 ft^2. When the area of the foundations (17,875 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 16,850 ft^2, or approximately 0.4 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to zinc at the BLA. Additionally, zinc was further evaluated in the terrestrial food chain model.

Thirty-two of the soil COPECs were also identified as bioaccumulative and were evaluated in the terrestrial food chain model.

4.5.3.2 Sediment

Thirty COPECs in sediment were carried forward into the BERA. When refined EPCs were compared with the ESLs, only one constituent, acetone, had a refined HQ greater than 1. In addition, ESLs were not available for four other constituents (barium; beryllium; thallium; and vanadium). The BERA results for sediment COPECs at the BLA are presented in Table A.4.ERA-5 and are discussed below:

Volatile Organic Compounds: One VOC, acetone, was retained in the BERA because the calculated HQ was greater than the benchmark value of 1. This VOC was detected in 1 out of 2 samples, and had a calculated HQ only slightly above the benchmark value of 1 (HQ=3). Consequently, adverse effects to aquatic life exposed to acetone are unlikely given the low calculated HQ.

Inorganics: Four inorganics (barium; beryllium; thallium; and vanadium) were retained in the BERA because an ESL was not available and no HQ could be calculated. All four constituents were detected in 2 out of 2 samples. While no background sediment data were collected, barium, beryllium, thallium, and vanadium were detected at concentrations below the corresponding soil background values established at the site (209 mg/kg; 1.02 mg/kg; 2.11 mg/kg; and 108 mg/kg, respectively). Consequently, adverse effects to aquatic life exposed to inorganics are unlikely given the similarity of detected concentrations with the site soil background values.

In addition to the COPEC discussed above, six pesticides, thirteen PAHs, and five inorganics were evaluated in the aquatic food chain model.

4.5.3.3 Surface Water

Eighteen COPECs in surface water were carried forward into the BERA. When refined EPCs were compared with the ESLs, 10 constituents (fluoranthene; pyrene; aluminum; arsenic; barium; copper; iron; lead; manganese; and mercury) had a refined HQ greater than 1. The BERA results for surface water COPECs at the BLA are presented in Table A.4.ERA-6 and are discussed below:

Polycyclic Aromatic Hydrocarbons: Two PAHs (fluoranthene and pyrene) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. Both PAHs were detected in 1 out of 4 samples, and had calculated HQs only slightly above the benchmark of 1 (HQs=2). Consequently, adverse effects to aquatic life exposed to PAHs are unlikely given the limited occurrence of the PAHs and the low calculated HQs.

Inorganics: Eight inorganics (aluminum; arsenic; barium; copper; iron; lead; manganese; and mercury) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1 or because an ESL was not available and no HQ could be calculated. These results are discussed below:

Aluminum – Aluminum was detected in 4 out of 4 surface water samples, with concentrations ranging from 0.14 mg/L to 0.549 mg/L. All four of these concentrations were above the ESL of 0.087 mg/L, however, the ESL used from USEPA (2008c) Region 3 was based on a water quality criterion protective of salmonids (i.e., coldwater habitat species of fish such as trout and salmon), which is likely overly conservative for the type of warmwater habitat (and associated aquatic species) that is prevalent in this locale. When an alternative screening value of 0.46 mg/L from Sample et al. 1996 was used, an HQ of less than 1 was calculated. This alternative screening value is based on the lowest chronic value of aquatic life, and is considered to be a more representative screening value for aluminum at the BLA. Based on these considerations, adverse effects to aquatic life exposed to aluminum are unlikely.

Arsenic – Arsenic was detected in 2 out of 4 surface water samples, with concentrations ranging from 0.0034 mg/L to 0.01 mg/L. Both samples were collected from the utility vaults in one of the BLA buildings. Arsenic was not detected in the stream samples collected in 2002. Only one of the detected concentrations was above the ESL of 0.005 mg/L, and the calculated HQ for the maximum concentration was only slightly above the benchmark value of 1 (HQ=2). Consequently, adverse effects to aquatic life exposed to arsenic are unlikely given the low calculated HQ. This COPEC was further evaluated in the aquatic food chain model.

Barium – Barium was detected in 4 out of 4 surface water samples, with concentrations ranging from 0.0588 mg/L to 0.0981 mg/L. While all four of these samples were greater than the ESL of 0.004 mg/L, the ESL used from USEPA (2008c) Region 3 was based on a secondary chronic value from Suter et al. 1996, and was established using an extremely limited dataset. An alternative aquatic screening value of 0.22 mg/L from USEPA (2003e) Region

5 was found, which is considered to be a more representative screening value. When this ESL was used, an HQ of less than 1 was calculated. This alternative screening value is based on the chronic standards for aquatic life, and is a more representative screening value for barium at the BLA. Based on these considerations, adverse effects to aquatic life exposed to barium are unlikely.

Copper – Copper was detected in 2 out of 4 surface water samples, with concentrations ranging from 0.646 mg/L to 0.828 mg/L. Both samples were collected from the utility vaults in one of the BLA buildings. Copper was not detected in the stream samples collected in 2002. While both detected concentrations were above the ESL of 0.009 mg/L, the ESL is based on a default hardness value of 100 mg/L. A site-specific hardness value of 207 mg/L (average in surface water samples collected from the stream at the BLA area) was used to calculate an ESL of 0.01668 mg/L. When this ESL was used, an HQ of 50 was calculated. It should be noted that the surface water samples were not filtered, and as such the results represent total copper. Therefore, it is not known what portion, if any, of the copper is in the dissolved (i.e., filtered) form. This is important because the dissolved form of copper (and most other metals) is the bioavailable form. It is likely that even though the total copper concentrations exceed the ESL, the dissolved (and therefore bioavailable) copper concentrations may in actuality not exceed the ESL. This is an uncertainty in the ERA evaluation. If aquatic organisms were exposed, on a chronic basis, to dissolved copper concentrations of 0.828 mg/L, then the potential exists for adverse effects to occur. However, given the fact that the water sample was collected from a utility vault rather than a true surface water body indicates that the potential for adverse effects is unlikely. This COPEC was further evaluated in the aquatic food chain model.

Iron – Iron was detected in 4 out of 4 surface water samples, with concentrations ranging from 0.274 mg/L to 0.742 mg/L. Two of these concentrations were above the ESL of 0.3 mg/L, and the calculated HQ for the maximum detected concentration was only slightly above the benchmark value of 1 (HQ=2). Consequently, adverse effects to aquatic life exposed to iron are unlikely given the low concentrations and calculated HQs.

Lead – Lead was detected in 4 out of 4 surface water samples, with concentrations ranging from 0.00034 mg/L to 0.247 mg/L. Only one of the detected concentrations (collected from a utility vault), was above the ESL of 0.0025 mg/L, which was based on a default hardness value of 100 mg/L. A site-specific hardness value of 207 mg/L (average at the BLA area) was used to calculate an ESL of 0.03411 mg/L. When this ESL was used, an HQ of 7 was calculated, which is only slightly above the benchmark value of 1. Furthermore, as previously stated, the surface water samples were not filtered, and as such the results represent total lead. Therefore, it is not known what portion, if any, of the lead is in the dissolved (i.e., filtered) form. It is possible that even though the total lead concentrations exceed the ESL, the dissolved (and therefore bioavailable) lead concentrations may in actuality not exceed the ESL. Consequently, adverse effects to aquatic life exposed to lead are unlikely given the low calculated HQ. Furthermore, the fact that the sample was collected from a utility vault rather than a true surface water body indicates that the potential for adverse effects are unlikely. This COPEC was further evaluated in the aquatic food chain model.

Manganese – Manganese was detected in 4 out of 4 surface water samples, with concentrations ranging from 0.0184 mg/L to 0.377 mg/L. Only one of these concentrations was above the ESL of 0.12 mg/L, and the calculated HQ for the maximum detected concentration was only slightly above the benchmark value of 1 (HQ=3). Consequently, adverse effects to aquatic life exposed to manganese are unlikely given the relatively low concentrations and the low calculated HQ.

Mercury – Mercury was detected in 1 out of 4 surface water samples, with a concentration of 0.0002 mg/L. The detected concentration was above the ESL of 0.000026 mg/L. This sample was collected from a utility vault in a BLA building. Mercury was not detected in the unnamed stream to the north of the BLA. Based on these considerations, it is unlikely that adverse effects to wildlife potentially exposed to mercury would occur at the BLA.

Of the COPECs identified for surface water, all but chromium were identified as bioaccumulative and evaluated in the aquatic food chain model.

4.5.4 Refinement of Assessment and Measurement Endpoints for Bioaccumulative COPECs

Food chain modeling was conducted at the BLA in order to evaluate the potential ecological effects of the bioaccumulative COPEC in soil, sediment, and surface water on the receptors identified in Section 2.4. COPECs identified in soil were evaluated in the terrestrial food chain, and COPECs identified in sediment and surface water were evaluated in the aquatic food chain. The results for both the maximum and refined scenarios of these models are presented in Tables A.4.ERA-7 through A.4.ERA-14, and the results of each of the refined scenarios are discussed in the subsections below.

4.5.4.1 Terrestrial Food chain Model

The refined scenario LOAEL and NOAEL HQs for all pesticides and most PAHs for both the short-tailed shrew (Tables A.4.ERA-7 and A.4.ERA-8) and the American robin (Tables A.4.ERA-9 and A.4.ERA-10) were less than 1, and the LOAELs and NOAELs for Aroclor 1254 were below 1 for the American robin.

Under the refined scenario for the American robin, all PAH HQs were below 1. For the short-tailed shrew, all LOAEL HQs were below 1 except dibenzo(a,h)anthracene (HQ=6). Similarly, all NOAEL HQs were below 10 except for dibenzo(a,h)anthracene (HQ=60). As previously noted, the TRV for dibenzo(a,h)anthracene was conservatively estimated from an acute toxicity test, and is therefore likely to overestimate risks to the short-tailed shrew. The ESL selected for evaluation of dibenzo(a,h)anthracene in this assessment is actually based on exposures to the masked shrew, and the maximum detected concentration is well below. Consequently, adverse effects to wildlife exposed to PAHs at the site are unlikely.

Under the refined scenario for Aroclor 1254 exposure for the short-tailed shrew, the NOAEL HQ and the LOAEL HQ were 5 and 0.5, respectively. The NOAEL, by definition, is a very conservative screening criterion. The LOAEL indicates a concentration above which adverse impacts to individual mammals may occur. While the HQ calculated using the conservative NOAEL is greater than 1, this HQ likely overestimates both the exposure of shrews and other insectivorous mammals to Aroclor 1254 at the BLA and the toxicity of Aroclor 1254 to these populations. The HQ calculated using the LOAEL (a more realistic indicator of toxicity) is less than 1, when using the UCL concentration in the refined scenario. Based on the consideration of NOAELs and LOAELs, the UCL concentrations, and the relatively limited spatial extent of affected soils associated with the perimeters of the concrete foundations, adverse impacts at the population-level are considered unlikely for the shrew or any other insectivorous mammals exposed to Aroclor 1254 at the BLA. Under the refined scenario for Aroclor 1254 exposure for the American robin, the NOAEL HQ and LOAEL HQ were both below 1, indicating that adverse affects at the population-level are considered unlikely for the robin or any other insectivorous birds exposed to Aroclor 1254 at the BLA.

Under the refined scenario for cadmium exposure for the short-tailed shrew, the NOAEL HQ and the LOAEL HQ were 2 and 20, respectively. The NOAEL is a very conservative screening criterion while the LOAEL indicates a concentration above which adverse impacts to individual mammals may occur. While the HQ calculated using the conservative LOAEL is greater than 1, as previously discussed, a closer examination of the location of those soil samples with elevated levels of cadmium indicates that the concentrations of cadmium in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation. The extent of affected soil available for ecological exposure is 16,850 ft^2, or approximately 0.4 acre. Based on the consideration of NOAELs and LOAELs and the relatively limited spatial extent of affected soils associated with the perimeters of the concrete foundations, adverse impacts at the population-level are considered unlikely for the shrew or any other insectivorous mammals potentially exposed to cadmium at the BLA. Under the refined scenario for cadmium exposure for the American robin, the NOAEL HQ and LOAEL HQ were both below 1, indicating that adverse affects at the population-level are considered unlikely for the robin or any other insectivorous birds exposed to cadmium at the BLA.

Under the refined short-tailed shrew scenario, the NOAEL HQ and LOAEL HQ for copper were both 10, the NOAEL HQ and LOAEL HQ for lead were 20 (NOAEL) and 2 (LOAEL), and the NOAEL HQ and LOAEL HQ for zinc were 70 (NOAEL) and 7 (LOAEL). Similarly, under the refined American robin scenario the NOAEL HQ and LOAEL HQ for lead were 10 (NOAEL) and 8 (LOAEL), the NOAEL HQ and LOAEL HQ for lead were 70 (NOAEL) and 7 (LOAEL), and the NOAEL HQ and LOAEL HQ for zinc were 20 (NOAEL) and 2 (LOAEL). The NOAEL is a very conservative screening criterion while the LOAEL indicates a concentration above which adverse impacts to individual mammals and birds may occur. While the HQs calculated using the conservative LOAEL were greater than 1, as previously discussed, a closer examination of the location of those soil samples with elevated levels of copper, lead, and zinc indicates that the concentrations of these metals in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation. The extent of affected soil available for ecological exposure is 16,850 ft^2, or approximately 0.4 acre. While these elevated levels of copper, lead, and zinc may cause localized affects to individual shrews and robins; overall, the total affected area is unlikely to pose a significant adverse ecological impact to ecological receptors at the population-level.

Based on the overall analysis of terrestrial food chain modeling HQs and consideration of the limited spatial extent of affected soils, adverse effects are not expected for short-tailed shrews (and other insectivorous mammals) and American robins (and other insectivorous birds) populations exposed to bioaccumulative COPECs in soil at the BLA.

4.5.4.2 Aquatic Food chain Model

The refined scenario LOAEL and NOAEL HQs for both the mink (Tables A.4.ERA-11 and A.4.ERA-12) and the great blue heron (Tables A.4.ERA-13 and A.4.ERA-14) were less than or equal to 1 for all bioaccumulative COPECs identified in sediment and/or surface water. These results indicate that mink and herons (or other piscivorous mammals and birds) exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of aquatic food chain modeling HQs, adverse effects are not expected for mink (and other piscivorous mammals) and great blue herons (and other piscivorous birds) populations exposed to bioaccumulative COPECs in sediment and/or surface water at the BLA.

4.5.5 Ecological Risk Summary

Screening-level and baseline risk assessments were completed for the BLA. After the SLERA, 53 constituents were selected as COPECs in surface soil, 30 constituents were selected as COPECs in sediment, and 18constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was bioaccumulative or an HQ could not be calculated because an ESL was not available. After the BERA, 52 constituents in surface soil, 29 constituents in sediment, and 17 constituents in surface water were retained because the HQs were greater than 1, the chemical was bioaccumulative or an HQ could not be calculated because an ESL was not available. Food chain modeling was evaluated for all those constituents identified as bioaccumulative.

Tables A.4.ERA-15 and A.4.ERA-16 summarize the constituents in surface soil, sediment, and surface water carried through the BERA and evaluated in the terrestrial and/or aquatic food chain model. As shown in Table A.4.ERA-15, Aroclor 1254 had NOAEL HQs greater than 1 and cadmium, copper, lead, and zinc had both NOAEL and LOAEL HQs greater than 1 for the short-tailed shrew. In addition, copper, lead, and zinc had both NOAEL and LOAEL HQs greater than 1 for the American robin. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents in surface soil, while the potential does exist for unacceptable risk to individual insectivorous mammals and birds exposed to surface soils containing affected concentrations of these COPECs, the potential for population-level effects is low. As shown in Table A.4.ERA-16, all constituents evaluated in the aquatic food chain refined scenarios had LOAEL and NOAEL HQs less than or equal to 1. These results indicate that individual mink and herons (or other piscivorous mammals and birds) potentially exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of the ERA for the BLA, the results indicate that adverse effects are not expected for wildlife at the site.

4.6 BLA Summary and Conclusions

For the purposes of the HHRA, surface soil, total soil, surface water and sediment were evaluated for both current and future land-use conditions. Under current land-use conditions, site worker exposures to surface soil, surface water, and sediment were evaluated. Under future conditions, the site worker exposures remained the same as the current exposures and construction worker, residential exposures to total soil, surface water, and sediment were evaluated.

The potential cumulative risk for site workers exposed to surface soil and sediment at the BLA under current and future land-use conditions was 1×10^{-4}, which is at the high end of USEPA's target risk range of 1×10^{-6} to 1×10^{-4} for health protectiveness at Superfund sites (USEPA, 1990). The potential cumulative HI for site workers was 0.8, which was less than the benchmark of 1.

The potential cumulative risk for construction workers exposed to total soil and sediment at the BLA under future land-use conditions was 7×10^{-6}, which is within the USEPA's target risk range of 1×10^{-6} to 1×10^{-4} for health protectiveness at Superfund sites (USEPA, 1990). The potential cumulative HI for construction workers of 3 exceeded the benchmark of 1 mostly due to exposure to copper.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water at the BLA is 1×10^{-3}, which is greater than the USEPA target risk range of 1×10^{-6} to 1×10^{-4}, due to the presence of benzo(a)pyrene.

The total cumulative HI for hypothetical future adult residents is equal to the benchmark of 1. The total cumulative HI for hypothetical future child residents is 12, which is greater than the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were above the benchmark of 1 in the central nervous system, whole body, and immune system, in the gastrointestinal tract, and in the eyes, nails, hair, and skin, due to the presence of copper and cobalt.

Bag Loading Area

Lead was a constituent of potential concern for each of the receptors considered in the BLA risk assessment. Exposure to lead is evaluated differently than the other constituents with the point of comparison based on a predicted blood lead level. For each of the receptors, exposure to lead resulted in predicted blood lead levels above the acceptable benchmark. Therefore, exposure to lead could result in an unacceptable risk.

Removal of the walls and roofs of the BLA buildings has exposed conductive flooring material to weather, causing it to degrade and wash onto the surrounding soils. Based on the results of activity-based air sampling conducted in soils surrounding some of those buildings, it appears that the presence of asbestos may present a potential risks for current and future site workers and hypothetical future residents.

A SLERA and BERA were completed for the BLA, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that while some of the NOAEL and LOAEL HQs were greater than 1, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, as well as the conservatism inherent in the dose calculation, effects of these COPECs at the population-level are unlikely at the BLA.

5. Igniter Assembly Area

5.1 Site Description and History

The IAA is located in the western portion of the RFAAP-NRU. Buildings at the site were used for igniter assembly, as well as the shipping and receiving of materials related to the IAA. The walls of the buildings were painted with lead-based paint. Deterioration of these materials may have provided a potential source of lead to the soils immediately surrounding the former building areas. The main igniter assembly buildings (Buildings 8102-1 through 8102-8) and multiple outparcel buildings at the IAA also had a conductive flooring material similar to the BLA. Locations of the conductive flooring on specified buildings are depicted on this figure. The buildings were constructed with conductive flooring to prevent build up of static electrical charges which could have potentially ignited explosive materials during assembly operations. This flooring material contains various heavy inorganics and asbestos and was exposed to the weather when the wooden roof and walls were removed from the buildings. As a result, the conductive flooring has degraded into a red powder-like substance very similar to what has been observed at the BLA. In many areas, the degraded conductive flooring material has washed off the concrete pads onto surrounding surface soils.

5.2 Physical Setting

The areas surrounding the main assembly buildings and multiple outparcel buildings are generally flat and vegetated with tall grass, shrubs, and pine trees. Previously maintained grassy areas have been allowed to revert to more natural conditions. Raised concrete sidewalks connect the assembly buildings with various outbuildings; however, none of these sidewalks were constructed with conductive flooring. A change-house/canteen (Building 8101) has been removed to its foundation. Building 8101 also contains no conductive flooring material. An engineered drainage system around the IAA consists of a series of culverts to divert water under the sidewalks to ditches which eventually drain into the unnamed creek that provides drainage for much of the RFAAP-NRU. However, the length of the unlined ditches suggests that runoff from normal rain events would infiltrate prior to arriving at the creek.

5.3 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. Risk assessment datasets for soil, sediment, and surface water for the IAA were prepared then summarized and statistically analyzed. Risk assessment datasets summaries highlighting the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPCs are presented in Tables A.5.Data-1 through Table A.5.Data-4.

5.4 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with constituents detected in soil and sediment samples collected at the IAA. No surface water samples were collected at the IAA; as a result, this medium was not evaluated. The risk assessment approach follows the Radford Army Ammunition Plant Final Master Work Plan (URS 2003).

The risk assessment approach is based on Virginia and USEPA guidance for risk assessments (VDEQ 2008; USEPA 2004a, 2000a, 1997a, 1992, 1991a, 1989). This section summarizes the occurrence of constituents in each medium and identifies COPCs at the IAA for the human health risk assessment; identifies the potential human exposure scenarios relevant to the IAA; and presents the estimated human health risks associated with the identified COPCs and the relevant human exposure scenarios at the IAA.

5.4.1 Selection of Constituents of Potential Concern

This section discusses the selection of COPCs for each medium.

5.4.1.1 Surface Soil

Surface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.5.HHRA-1 presents the selection of surface COPCs for the HHRA. Twenty-seven constituents were identified as COPCs.

Four VOCs (3-octanone; acetone; d-limonene; and methylene chloride) were detected in surface soil. Acetone and methylene chloride were both detected at concentrations below their USEPA (2009a) residential soil RSL values. No USEPA (2009a) residential soil RSL values were available for 3-octanone or d-limonene. As a result, 3-octanone and d-limonene were identified as COPCs for surface soil.

Nine SVOCs (2,4-dinitrotoluene; benzoic acid; bis[2-ethylhexyl]phthalate; butylbenzylphthalate; carbazole; dibenzofuran; diethylphthalate; di-n-butylphthalate; and di-n-octylphthalate) were detected in surface soil. Only 2,4-dinitrotoluene and bis(2-ethylhexyl)phthalate were detected at concentrations that were greater than their

USEPA (2009a) residential soil RSL values. In addition, a USEPA (2009a) residential soil RSL value was not available for carbazole; as a result, these three constituents were identified as COPCs for surface soil.

Three explosives (1,3,5-trinitrobenzene; 4-amino-2,6-dinitrotoluene; and nitroglycerine) were detected in surface soil. All three of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values and were not identified as COPCs for surface soil.

Thirteen pesticides (4,4'-DDD; 4,4'-DDE; 4,4'-DDT; beta-BHC; delta-BHC; alpha-chlordane; gamma-chlordane; dieldrin; endosulfan II; endrin; endrin ketone; heptachlor epoxide; and methoxyclor) were detected in surface soil. None of the constituents were detected at concentrations above the USEPA (2009a) residential soil RSL values, and as a result, were not identified as COPCs in surface soil.

Eighteen PAHs (1-methylnaphthalene; 2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in surface soil. Seven of these detected constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene) had maximum concentrations greater than the USEPA (2009a) residential soil RSL values and were identified as COPCs for surface soil.

Two PCBs (Aroclor 1254 and Aroclor 1260) were detected in surface soil. Both of these constituents were detected at concentrations above the USEPA (2009a) residential soil RSL values and were identified as COPCs for surface soil.

Twenty-three inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; silver; sodium; thallium; vanadium; and zinc) were detected in surface soil. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Sixteen of these constituents (aluminum; antimony; arsenic; barium; cadmium; chromium; cobalt; copper; iron; lead; manganese; mercury; nickel; thallium; vanadium; and zinc) were greater than the USEPA (2009a) residential soil RSL values. However, manganese, thallium, and vanadium were all detected below the background concentrations. As a result, only aluminum, antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, mercury, nickel, and zinc were identified as COPCs for surface soil.

Finally, asbestos has also been detected in surface soils around some of the buildings in the IAA in areas where conductive flooring has degraded into a red powder-like material that has washed onto the surrounding soils adjacent to those buildings. Soil sampling and activity-based air sampling have been conducted in selected areas of the IAA and are discussed in Section 7.4.9 of the RI. The results of this sampling indicate that asbestos is also a COPC for surface soil at this site.

5.4.1.2 Combined Surface and Subsurface Soil

Combined surface and subsurface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.5.HHRA-2 presents the selection of combined surface and subsurface soil COPCs for the HHRA. Twenty-seven constituents were identified as COPCs in combined surface and subsurface soil.

Five VOCs (3-octanone; acetone; d-limonene; methylene chloride, and toluene) were detected in combined surface and subsurface soil. Acetone and methylene chloride were both detected below their USEPA (2009a) residential soil RSL values. USEPA (2009a) residential soil RSL values were not available for 3-octanone or d-limonene. As a result, only 3-octanone and d-limonene were identified as COPCs for combined surface and subsurface soil.

Nine SVOCs (2,4-dinitrotoluene; benzoic acid; bis[2-ethylhexyl]phthalate; butylbenzylphthalate; carbazole; dibenzofuran; diethylphthalate; di-n-butylphthalate; and di-n-octylphthalate) were detected in combined surface and subsurface soil. Only 2,4-dinitrotoluene and bis(2-ethylhexyl)phthalate were detected at concentrations that were greater than their USEPA (2009a) residential soil RSL values. In addition, a USEPA (2009a) residential soil RSL value was not available for carbazole; as a result, these three constituents were identified as COPCs for combined surface and subsurface soil.

Three explosives (1,3,5-trinitrobenzene; 4-amino-2,6-dinitrotoluene; and nitroglycerine) were detected in combined surface and subsurface soil. All three of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values.

Thirteen pesticides (4,4'-DDD; 4,4'-DDE; 4,4'-DDT; beta-BHC; delta-BHC; alpha-chlordane; gamma-chlordane; dieldrin; endosulfan II; endrin; endrin ketone; heptachlor epoxide; and methoxyclor) were detected in combined surface and subsurface soil. All 13 of these constituents were below the USEPA (2009a) residential soil RSL values.

Eighteen PAHs (1-methylnaphthalene; 2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in combined surface and subsurface soil. Seven of these detected constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene) were detected at concentrations greater than the USEPA (2009a) residential soil RSL values and were identified as COPCs for combined surface and subsurface soil.

Two PCBs (Aroclor 1254 and Aroclor 1260) were detected in combined surface and subsurface soil. Both of these constituents were detected at concentrations above the USEPA (2009a) residential soil RSL values and were identified as COPCs for combined surface and subsurface soil.

Twenty-three inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; silver; sodium; thallium; vanadium; and zinc) were detected in combined surface and subsurface soil. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Sixteen of these constituents (aluminum; antimony; arsenic; barium; cadmium; chromium; cobalt; copper; iron; lead; manganese; mercury; nickel; thallium; vanadium; and zinc) were greater than the USEPA (2009a) residential soil RSL values. However, manganese, thallium, and vanadium were all detected at concentrations below the background concentrations. As a result, only aluminum, antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, mercury, nickel, and zinc were identified as COPCs for combined surface and subsurface soil.

5.4.1.3 Sediment

Sediment COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.5.HHRA-3 presents the selection of sediment COPCs for the HHRA. Six constituents were identified as COPCs in sediment.

Eighteen inorganics (aluminum; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel;

potassium; vanadium; and zinc) were detected in sediment. Six of these constituents (aluminum; arsenic; cobalt; iron; manganese; and vanadium) were detected at concentrations greater than the USEPA (2009a) residential soil RSL values, and three constituents (calcium; magnesium; and potassium) were identified as essential nutrients. Consequently, only aluminum, arsenic, cobalt, iron, manganese, and vanadium were identified as COPCs for sediment.

5.4.2 Summary of Selected Constituents of Potential Concern

Twenty-seven constituents were selected as COPCs in surface soil and combined surface and subsurface soil at the IAA, including two VOCs (3-octanone and d-limonene), three SVOCs (2,4-dinitrotoluene; bis[2-ethylhexyl]phthalate; and carbazole), seven PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene), two PCBs (Aroclor 1254 and Aroclor 1260), and thirteen inorganics (aluminum; antimony; arsenic; barium; cadmium; chromium; cobalt; copper; iron; lead; mercury; nickel; and zinc).

Six inorganics were selected as COPCs in sediment at the IAA, including aluminum, arsenic, cobalt, iron, manganese, and vanadium.

5.4.3 Determination of Exposure Point Concentrations

Twenty-seven constituents were selected as COPCs in both surface soil and combined surface and subsurface soil, and seven constituents were selected as COPCs in sediment because the maximum detected concentrations were greater than the corresponding USEPA (2009a) RSL or no RSL was available. The EPCs for these COPCs are summarized in Table A.5.HHRA-4.

5.4.4 Human Health Risk Characterization

Exposure to the constituents detected in soil and sediment COPCs were evaluated for direct contact. VOCs identified as COPCs in the IAA were also evaluated for inhalation via vapor migration into buildings. Two VOCs, 3-octanone and d-limonene, were identified as soil COPCs at the IAA. Those two COPCs do not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area.

Results of the risk characterization are discussed below. The ELCRs and non-cancer hazards are summarized in Table A.5.HHRA-12. The blood lead level model estimates for each potentially exposed receptor included in the risk assessment for the IAA are summarized in Table A.5.HHRA-16.

5.4.4.1 Site Worker

A current or future site worker could be present at the IAA area, and could be exposed to constituents detected in surface soil or sediment. The ELCR and non-cancer hazard index for site worker exposure to each medium are presented in Tables A.5.HHRA-5 and A.5.HHRA-6. The ELCRs for surface soil and sediment are all below or within the USEPA target risk range, and the HIs for each medium are all at or below the benchmark value of 1.

The total cumulative ELCR for site workers exposed to surface soil and sediment at the IAA is 1×10^{-4}, which is equal to the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 1, which is equal to the benchmark of 1.

The 50th percentile blood lead level estimates for the site worker receptor was at 2.8 µg/dL which is well below the benchmark of 10 µg/dL, and the 95th percentile fetal blood lead level was approximately equal to the benchmark of 10 µg/dL, as summarized in A.5.HHRA-13.

5.4.4.2 Hypothetical Future Construction Worker

A hypothetical future construction worker could be present at the IAA area, and could be exposed to combined surface and subsurface soil. The ELCR and non-cancer hazard index for hypothetical future construction worker exposure to soil are presented in Table A.5.HHRA-7. As presented in the table above, the ELCR for combined surface and subsurface soil is within the USEPA target risk range, and the HI is above the benchmark value of 1.

The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the IAA is 6×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 3, which is above the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were all below or equal to the benchmark of 1. The 50th percentile blood lead level estimates for the construction worker receptor was at 2.8 µg/dL which is well below the benchmark of 10 µg/dL and the 95th percentile fetal blood lead level was approximately equal to the benchmark, as seen in Table A.5.HHRA-15.

5.4.4.3 Hypothetical Future Residents

A hypothetical future resident could be present at the IAA area, and could be exposed to combined surface and subsurface soil or sediment. The ELCR and non-cancer hazard index for hypothetical future adult or child resident exposure to each medium are presented in Tables A.5.HHRA-8 through A.5.HHRA-11 and summarized in Table A.5.HHRA-12. The ELCR for sediment is within the USEPA target risk range; however, the ELCRs for combined surface and subsurface soil were greater than the USEPA risk range. The HIs for each medium are all at or below the benchmark value of 1, with the exception of child resident exposure to combined surface and subsurface soil.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil and sediment at the IAA is 5×10^{-4}, which is above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}.The primary risk driver is 2,4-dinitrotoluene in soil. Other contributors to the excess lifetime cancer risks were benzo(a)pyrene, Aroclor 1254, and arsenic.

The total cumulative HI for hypothetical future adult residents is 1, which is equal to the benchmark. When the hazards were segregated by target organ or critical effect, all of the HIs were less than 1. The total cumulative HI for hypothetical future child residents is 13, which is above the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were greater than the benchmark of 1 in the central nervous system, whole body, and immune system, in the blood, in the gastrointestinal tract, and in the eyes, nails, hair, and skin. The risk drivers for non-cancer hazard are Aroclor 1254, copper, 2,4-dinitrotoluene, and cobalt.

The 50^{th} percentile blood lead level estimates for the hypothetical adult resident receptor was calculated to be 3.2 µg/dL which is well below the benchmark of 10 µg/dL, and the 95^{th} percentile fetal blood lead levels was calculated to be 11 µg/dL slightly above the benchmark of 10 µg/dL, as seen in Table A.5.HHRA-14. The range of annual mean blood lead level estimates over seven years for the child receptor was 4.4µg/dL to 8.2 µg/dL, which is below the benchmark of10 µg/dL, as seen in Table A.5.HHRA-14. However, exposure of a child over a seven year period resulted in a geometric mean blood lead concentration of 6.4 µg/dL, below the 10 µg/dL benchmark, but a prediction of 17 percent of the population having blood lead concentrations above the 10 µg/dL benchmark. Table A.5.HHRA-14 summarizes the input assumptions to and outputs from the lead modeling for the child resident.

5.4.5 Evaluation of Asbestos

As discussed in Section 4.4.5, ARCADIS conducted an additional investigation in July 2009 to facilitate the evaluation of potential health risks associated with asbestos in soil. During that investigation, ARCADIS collected delineation soil samples adjacent to a number of buildings in the IAA where asbestos had either been detected in soil or there were no historical sampling data. In addition, ARCADIS conducted activity-based air sampling at two buildings in the IAA (Building 5 and Building 8102) to determine if soil disturbance in those areas would result in unacceptable air concentrations of asbestos.

In Section 4.4.5, risk-based AALs were calculated, using USEPA (2008f) methodology, for the four exposure scenarios that have been evaluated for the IAA. These AALs, based on the 1E-04 risk level that represents the upper end of USEPA acceptable risk range, were 0.007 f/cc for the current/future site worker, 0.2 f/cc for the future hypothetical construction worker, 0.002 f/cc for the future hypothetical child resident, and 0.001 f/cc for the future hypothetical adult resident.

Results of the air sampling indicate that all air samples in the sampling grids adjacent to Building 5 were non-detect for asbestos, as were the delineation soil samples collected in this area. As a result, all of these samples were below the risk-based AALs for current, future, and future hypothetical exposure scenarios, indicating that risks due to asbestos were below levels of concern in this area.

Soil samples adjacent to Building 8102, however, had measureable concentrations of asbestos in the grid located 0-10 feet from the building perimeter. The total asbestos air concentrations measured at IAA8102-AA1 and IAA8102-AP1 were 0.0078 and 0.053 f/cc, respectively. The two samples collected from the grid located 10-20 feet from the building perimeter were non-detect for asbestos. The average concentration using all four samples is 0.015 f/cc. All of these exceed the AAL of 0.007 f/cc (based on a 1E-04 risk level) calculated for the current and future site worker, as well as the range of AALs calculated for hypothetical future residents. They do not exceed the AAL of 0.2 calculated for the hypothetical future construction worker.

These results indicate that the presence of asbestos in the soils closest to Building 8102 may result in unacceptable air concentrations if those soils are subject to intensive disturbance. Consequently, they may potentially present an unacceptable risk to individuals who are engaged in soil-disturbance activities there.

5.4.6 Human Health Risk Summary

Table A.5.HHRA-12 summarizes the calculated cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the IAA. As shown in the table below, the total ELCR values for all surface soil, combined surface and subsurface soil and sediment exposures for each exposure scenario are below or within the benchmark range of 10^{-6} to 10^{-4} for cancer risk, with the exception of hypothetical future residential exposure to combined surface and subsurface soil. The primary contributor to the risk estimates is 2,4-dinitrotoluene.

Summary of Calculated ELCRs and HIs for Receptor Exposure Scenarios

RECEPTOR/EXPOSURE MEDIUM – SCENARIO	ELCR	HI
Site Worker		
Surface Soil - Direct Contact	1E-04	1
Sediment – Wading	8E-07	0.01
TOTAL SITE RISKS (Site Worker):	**1E-04**	**1**
Hypothetical Future Construction Worker		
Combined Surface and Subsurface Soil - Direct Contact	6E-06	3
TOTAL SITE RISKS (Construction Worker):	**6E-06**	**3**
Hypothetical Future Adult Resident		
Combined Surface and Subsurface Soil - Direct Contact	-	1
Sediment – Wading	-	0.02
TOTAL SITE RISKS (Adult Resident):	**-**	**1**
Hypothetical Future Child Resident		
Combined Surface and Subsurface Soil - Direct Contact	-	13
Sediment – Wading	-	0.1
TOTAL SITE RISKS (Child Resident):	**-**	**13**
Hypothetical Future Resident (Adult and Child)		
Combined Surface and Subsurface Soil - Direct Contact	5E-04	-
Sediment – Wading	3E-06	-
TOTAL SITE RISKS (Aggregate Resident):	**5E-04**	**-**

The total HI values for all surface soil, combined surface and subsurface soil, and sediment exposures for each exposure scenario are at or below the benchmark of 1 for non-cancer hazard, with the exception of hypothetical future construction worker and hypothetical future child resident exposure to combined surface and subsurface soil. When the HI is segregated into target site and critical effects for the hypothetical future construction worker, hazards were all at or below the benchmark of 1. The primary contributors to the hazards above 1 for the hypothetical future child resident are Aroclor 1254, copper, 2,4-dinitrotoluene and cobalt.

The results of the risk assessment indicated that under industrial exposure scenarios the calculated ELCRs, noncancer hazards, and predicted blood lead levels were all within target risk ranges or less than or equal to benchmarks.

The results of the risk assessment for hypothetical future residential receptors indicated that 2,4-dinitrotoluene, Aroclor 1254, cobalt, copper, and lead were constituents of concern for both adult and child residents. 2,4-Dinitrotoluene was detected in two of thirty-six samples, with the two detections collected from two depths at sampling location 504360 during the December 1997 sampling event. No other detections of this constituent were confirmed during the subsequent sampling events. Finally, only the maximum concentration of cobalt (422 mg/kg) fell outside of the background concentration range of 5.9 mg/kg to 130 mg/kg.

Summary of Estimated Blood Lead Levels for Receptor Exposure Scenarios

RECEPTOR	Estimated Blood Lead Level (µg/dL)		
	Adult	Child	Fetus
	50th percentile	Range	95th percentile
SOIL			
Site Worker	2.8	–	10
Hypothetical Future Construction Worker	2.8	–	10
Hypothetical Future Child	–	4.4 - 8.2	–
Hypothetical Future Adult	3.2	–	11

As discussed in Section 5.1, removal of the walls and roofs of the IAA buildings has exposed conductive flooring to weather, causing it to degrade and wash onto the surrounding soils. Based on the results of activity-based air sampling conducted in soils surrounding some of those buildings, it appears that the presence of asbestos in soil may present an unacceptable risk for current and future site workers and hypothetical future future residents.

5.5 Ecological Risk Assessment

The purpose of the ERA is to evaluate whether ecological receptors may be adversely impacted by exposure to site-related constituents detected in surface soil, sediment, and surface water at the IAA. The ERA approach is based on the Master Work Plan (URS 2003) in compliance with CERCLA/SARA. The ERA was conducted in a manner consistent with Virginia policy and USEPA guidance for ecological risk assessment (USEPA 2001a; 2000b; 1997c). This ERA is intended to provide input for risk management decision-making for the IAA, while maintaining a conservative approach protective of wildlife populations and communities. In accordance with USEPA guidance, the ERA for the IAA commenced with a SLERA and then concluded with BERA (USEPA 1997c).

This section summarizes the occurrence of constituents in each medium and identifies COPECs at the IAA for the ERA; identifies the potential ecological exposure scenarios relevant to the IAA; and presents the estimated ecological risks associated with the identified COPECs and the relevant ecological exposure scenarios at the IAA. Methodologies for data summary and selection of COPECs, exposure assessment, and toxicity assessment for the ERA were presented in Section 2.4.

5.5.1 Selection of Constituents of Potential Ecological Concern

This section discusses the selection of COPECs for each medium. Risks to ecological receptors are calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the hazard quotient (HQ), is a conservative surrogate for the assessment endpoints identified in Section 2.4. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse ecological effects are unlikely (USEPA 1997c). HQs greater than 1 indicate that further evaluation is warranted. Therefore, the constituents with HQs greater than 1 are carried forward as COPECs into the BERA. Because the majority of the ESLs measure direct exposures and do not take into account exposures to upper trophic level species, chemicals identified as bioaccumulative were also carried forward as COPECs regardless of whether or not the associated HQ was greater than 1. Finally, as previously described, soil concentrations of inorganic constituents were compared to background soil concentrations; those with concentrations below background were not considered as COPEC. The COPEC selection process for the IAA are summarized in the subsections below.

Data were not collected for surface water at the IAA, therefore COPECs are only presented for soil and sediment.

5.5.1.1 Surface Soil

Surface soil COPECs were selected by comparing the analytical data with USEPA (2005b) EcoSSLs, USEPA (2003e) Region 5 ESLs, and ORNL values (Efroymson et al. 1997a,b) for surface soil. Table A.5.ERA-1 presents the selection of surface soil COPECs for the ERA. Fifty-three constituents were identified as COPECs in surface soil.

Four VOCs (3-octanone; acetone; d-limonene; and methylene chloride) were detected in surface soil. Acetone and methylene chloride both had an HQ less than or equal to 1; however, no ESLs were available for 3-octanone or d-limonene and so HQs could not be calculated. As a result, 3-octanone and d-limonene were identified as COPECs for surface soil.

Nine SVOCs (2,4-dinitrotoluene; benzoic acid; bis[2-ethylhexyl]phthalate; butylbenzylphthalate; carbazole; dibenzofuran; diethylphthalate; di-n-butylphthalate; and di-n-octylphthalate) were detected in surface soil. Four of these constituents (2,4-dinitrotoluene; bis[2-ethylhexyl]phthalate; diethylphthalate; and di-n-butylphthalate) had an HQ greater than 1. In addition, ESLs were not available for benzoic acid, carbazole, and dibenzofuran, and so HQs could not be calculated. As a result, 2,4-dinitrotoluene, benzoic acid, bis[2-ethylhexyl]phthalate, carbazole, dibenzofuran, diethylphthalate, and di-n-butylphthalate were identified as COPECs for surface soil.

Three explosives (1,3,5-trinitrobenzene; 4-amino-2,6-dinitrotoluene; and nitroglycerine) were detected in surface soil. An ESL was not available for nitroglycerine and so an HQ could not be calculated and it was identified as a COPEC for surface soil.

Thirteen pesticides (4,4'-DDD; 4,4'-DDE; 4,4'-DDT; beta-BHC; delta-BHC; alpha-chlordane; gamma-chlordane; dieldrin; endosulfan II; endrin; endrin ketone; heptachlor epoxide; and methoxyclor) were detected in surface soil. Only two of these constituents, dieldrin and endrin, had an HQ greater than 1. In addition, all of the detected pesticides except gamma-chlordane and endrin ketone were identified as bioaccumulative, therefore, 4,4'-DDD; 4,4'-DDE; 4,4'-DDT; beta-BHC; delta-BHC; alpha-chlordane; dieldrin; endosulfan II; endrin; heptachlor epoxide; and methoxyclor were identified as COPECs in surface soil.

Eighteen PAHs (1-methylnaphthalene; 2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in surface soil. Three of these detected constituents (benzo[a]pyrene; chrysene; and naphthalene) had an HQ greater than 1, however, all except 1-methylnaphthalene and 2-methylnaphthalene were identified as bioaccumulative and, therefore, identified as COPECs for surface soil.

Two PCBs (Aroclor 1254 and Aroclor 1260) were detected in surface soil. Neither of these constituents had ESLs available and both were identified as bioaccumulative, therefore, they were identified as COPECs for surface soil.

Twenty-three inorganics were detected in surface soil. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Seventeen of the detected constituents (aluminum, antimony; arsenic; barium; cadmium; chromium; cobalt; copper; lead; manganese; mercury; nickel; selenium; silver; thallium; vanadium; and zinc) had an HQ greater than 1, and one constituent (iron) did not have an ESL available and so an HQ could not be calculated. However, four constituents (aluminum, manganese; thallium; and vanadium) had maximum concentrations less than their respective background concentration established at the site. As a result, antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, mercury, nickel, selenium, silver, and zinc were identified as COPECs for surface soil.

5.5.1.2 Sediment

Sediment COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Sediment Screening Levels; ORNL values (Jones et al. 1997); and USEPA (2003e) Region 5 Ecological Screening Levels for sediment. Table A.5.ERA-2 presents the selection of sediment COPECs for the ERA. Eighteen inorganics (aluminum; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; vanadium; and zinc) were detected in sediment. Three constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; and potassium) and therefore were identified as non-toxic and not evaluated further. Only one constituent (iron) had an HQ greater than 1, and three constituents (barium; beryllium; and vanadium) did not have an ESL available and an HQ could not be calculated. In addition, seven constituents were identified as bioaccumulative. Therefore, arsenic, barium, beryllium,cadmium, chromium, copper, iron, lead, nickel, vanadium, and zinc were identified as COPECs for sediment.

5.5.2 Summary of Selected Constituents of Potential Ecological Concern

Fifty-three constituents were selected as COPECs in surface soil and eleven constituents were selected as COPECs in sediment because the HQs were greater than 1, the chemical was bioaccumulative or an HQ could not be calculated because an ESL was not available.

5.5.3 Refinement of Risk Calculations for Direct Contact COPECs

The list of COPECs identified in the BERA was reevaluated by recalculating the HQs. The refined HQs were calculated for the COPECs identified in the SLERA using refined EPCs. Constituents identified as COPECs in the BERA that were bioaccumulative were carried forward into food chain models. The results of the recalculation of the HQs for the IAA are summarized in the subsections below.

5.5.3.1 Surface Soil

Fifty-three COPECs in surface soil were carried forward into the BERA. When refined EPCs were compared with the ESLs, 15 constituents (2,4-dinitrotoluene; bis[2-ethylhexyl]phthalate; diethylphthalate; di-n-butylphthalate; benzo[a]pyrene; naphthalene; antimony; barium; cadmium; chromium; cobalt; copper; lead; mercury; and zinc) had a refined HQ greater than 1. In addition, ESLs were not available for 9 other constituents (3-octanone; d-limonene; benzoic acid; carbazole; dibenzofuran; nitroglycerine; Aroclor 1254; Aroclor 1260;; and iron). The BERA results for surface soil COPECs at the IAA are presented in Table A.5.ERA-3.

Volatile Organic Compounds: Two VOCs (3-octanone and d-limonene) were retained in the BERA because an ESL was not available and so HQs could not be calculated. These VOCs were detected in 4 out of 4 and 3 out of 3 surface soil samples, respectively. Due to the low detected concentrations for these two VOCs (i.e., < 1 mg/kg) and their physical and chemical properties (e.g., relatively high vapor pressure and solubility; relatively low Kow and low potential to bioaccumulate), adverse effects to wildlife due to potential VOC exposure are considered unlikely.

Semi-Volatile Organic Compounds: Seven SVOCs (2,4-dinitrotoluene; benzoic acid; bis[2-ethylhexyl]phthalate; carbazole; dibenzofuran; diethylphthalate; and di-n-butylphthalate) were retained in the BERA because the calculated HQ was greater than the benchmark value of 1 or because an ESL was not available and so HQs could not be calculated. These results are discussed below:

2,4-Dinitrotoluene – 2,4-Dinitrotoluene was detected in 1 out of 30 surface soil samples, with a concentration of 48 mg/kg. While this concentration was above the ESL of 1.28 mg/kg, given the low frequency of detection, it is unlikely that potential exposure to 2,4-dinitrotoluene will cause adverse effects to wildlife.

Benzoic acid – Benzoic acid was detected in 7 out of 22 surface soil samples, with concentrations ranging from 0.1 mg/kg to 0.3 mg/kg. While no ESL was available and an HQ could not be calculated, given the low frequency of detection, and the very low concentrations (i.e., < 1 mg/kg), it is unlikely that potential exposure to benzoic acid will cause adverse effects to wildlife.

Bis(2-ethylhexyl)phthalate – Bis(2-ethylhexyl)phthalate was detected in 23 out of 31 surface soil samples, with concentrations ranging from 0.03 mg/kg to 750 mg/kg. Only eight of these concentrations were above the ESL of 0.92594 mg/kg. In addition, bis(2-ethylhexyl)phthalate was also detected in the laboratory blank. Consequently, adverse effects to wildlife exposed to bis(2-ethylhexyl)phthalate are unlikely given the low concentrations and the uncertainty that the VOC was actually detected in the sediment samples.

Carbazole – Carbazole was detected in 5 out of 22 surface soil samples, with concentrations ranging from 0.016 mg/kg to 2.4 mg/kg. While no ESL was available and an HQ could not be calculated, given the low frequency of detection and the relatively low detected concentrations, it is unlikely that potential exposure to carbazole will cause adverse effects to wildlife.

Dibenzofuran – Dibenzofuran was detected in 4 out of 20 surface soil samples, with concentrations ranging from 0.018 mg/kg to 0.74 mg/kg. While no ESL was available and an HQ could not be calculated, given the low frequency of detection and the very low concentrations (i.e., < 1 mg/kg), it is unlikely that potential exposure to dibenzofuran acid will cause adverse effects to wildlife.

Di-n-butylphthalate – Di-n-butylphthalate was detected in 2 out of 22 surface soil samples, with concentrations ranging from 0.07 mg/kg to 0.31 mg/kg. Only one of these concentrations was above the ESL of 0.15 mg/kg, and this concentration was qualified with a B flag, indicating that the constituent was also detected in the blank. Based on these considerations, it is unlikely that di-n-butylphthalate will cause adverse effects to wildlife.

Explosives: One explosive, nitroglycerine, was retained in the BERA because an ESL was not available and so an HQ could not be calculated. This constituent was detected in 1 out of 19 samples, at a concentration of 0.57 mg/kg. Due to the low frequency of detection and the low detected concentration, adverse effects to wildlife potentially exposed to explosives are unlikely.

Polycyclic Aromatic Hydrocarbons: Two PAHs (benzo[a]pyrene and naphthalene) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. Calculated HQs for these PAHs were 2 and 4, respectively. Although these two PAHs were detected relatively frequently (55% detection frequency for benzo[a]pyrene and 45% for naphthalene), as discussed previously the ESLs for these constituents were obtained from USEPA (2003e) Region 5, and are especially conservative values based on toxicity to the masked shrew. When site-specific food chain modeling was evaluated for PAHs, the HQs for the refined scenarios were below the benchmark value of 1 for the LOAEL for all chemicals and for all but two chemicals for the NOAEL. These results are further discussed in the sections below.

Naphthalene was not identified as a bioaccumulative COPEC. The HQ calculated using the USEPA (2003e) Region 5 value for this PAH was 4, which is only slightly above the benchmark of 1. While alternate ESLs were not available for naphthalene, additional toxicologically-based benchmarks were available from Sample et al (1996) for other PAHs. The benchmarks developed by Sample et al (1996) are NOAEL-based dietary benchmarks for mammals exposed to a constituent via ingestion of food. Since naphthalene is not a bioaccumulative COPEC, assuming the naphthalene concentration in all food items is equivalent to the concentration in surface soil provides a conservative estimate of dietary exposure. That is, the receptor would have to have a diet of 100 percent soil to receive the dose associated with the Sample et al (1996) benchmark. The NOAEL benchmark values for benzo(a)pyrene, the most conservative of the PAHs, ranged from 1.98 mg/kg to 8.0 mg/kg. The EPC for naphthalene, 0.357 mg/kg, was below this range of acceptable concentrations.

Consequently, adverse effects to wildlife exposed to PAHs at the site are unlikely given the site-specific food chain model results and the similarity of naphthalene concentrations with those below NOAEL-based benchmark values.

Polychlorinated Biphenyls: Two PCBs (Aroclor 1254 and Aroclor 1260) were retained in the BERA because ESLs were not available and so HQs could not be calculated. Aroclor 1254 was detected in 12 out of 35 surface soil samples, with concentrations ranging from 0.0049 mg/kg to 12 mg/kg. Aroclor 1260 was only detected in 3 of 27 samples, with concentrations ranging from 0.37 mg/kg to 1 mg/kg.

While there are no Aroclor-specific ESLs from Region 5, Region 5 does provide an ESL of 0.000332 mg/kg for PCBs as a group. The maximum and UCL concentrations for Aroclor 1254 and the maximum concentration for Aroclor 1260 at the IAA are above this ESL; however, site-specific food chain modeling for the short-tailed shrew and American robin (Section 5.7.4), using conservative exposure assumptions, indicates that the potential risk from exposure to both Aroclor 1254 and 1260 at the IAA is very low. Although there are some soil samples at the IAA with elevated concentrations of PCBs, specifically Aroclor 1254, a closer examination of the location of those samples in relation to the concrete building foundations, and their spatial extent indicates that the concentrations of Aroclor 1254 (and other PCBs) in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (i.e., in general, concentrations decrease with distance from the foundations; Figure 5-1). For example, in sample location 504312 (located approximately 1-ft from the building foundation), the concentration of Aroclor 1254 is 0.89 mg/kg, compared to 0.04 mg/kg in sample location IASB15 (located approximately 10 feet away from the foundation). This trend is repeated in other sample locations (i.e., 502436, which is located approximately 3 feet of the foundation, versus 502460, which is approximately 5 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 29 buildings at the IAA encompass an area of 72,191 ft^2. When the area of the foundations (37,641 ft2) is subtracted, the extent of affected soil available for ecological exposure is 34,550 ft2, or approximately 0.8 acre. While very small areas may provide occasional foraging habitat or cover, they are unlikely to support a viable population or represent a significant percentage of the overall exposure. Of the receptors identified for consideration at the site, the short-tailed shrew would have the smallest foraging range, however, even that species requires approximately 1 acre (0.0015 mi^2; USEPA, 1993d). Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to PCBs at the IAA.

<u>Inorganics</u>: Ten inorganics (antimony; barium; cadmium; chromium; cobalt; copper; iron; lead; mercury; and zinc) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1, or an HQ could not be calculated because an ESL was not available. These results are discussed below:

<u>Antimony</u> – Antimony was detected in 30 out of 96 surface soil samples, with concentrations ranging from 0.21 mg/kg to 16.9 mg/kg. Twenty-three of these concentrations were above the ESL of 0.27 mg/kg. While site-specific background values for antimony were not available, these detected concentrations were compared to the mean reported soil inorganic background

concentrations developed for Virginia (USEPA 1995). The EPC for antimony at the IAA was 1.2 mg/kg, which was equal to the reported background soil concentration of antimony in Virginia (USEPA 1995). Consequently, adverse effects to wildlife exposed to antimony are unlikely given the similarity of detected concentrations with the state background value.

Barium – Barium occurs naturally in soil at the RFAAP-NRU and is also one of the known components in the conductive flooring material at the BLA and IAA. Barium was detected in 99 out of 99 surface soil samples, with concentrations ranging from 8.5 mg/kg to 11,800 mg/kg. Seventeen of these concentrations were above the ESL of 330 mg/kg, and twenty-eight concentrations were above the background value of 209 mg/kg established at the site. Although there are some soil samples at the IAA with elevated concentrations of barium, a closer examination of the location of those samples in relation to the concrete building foundations, and their spatial extent indicates that the concentrations of barium (and other metals) in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (i.e., in general, concentrations decrease with distance from the foundations; Figure 5-2). For example, in sample location SS-12 (located approximately 5 ft from the foundation of the building) the concentration of barium is 3,220 mg/kg, compared to 72.9 mg/kg in sample location IASS02 (located approximately 15 feet away from the foundation), which is below the background value of 209 mg/kg established at the site. This trend is repeated in other sample locations (i.e., IATP2A/C, which is located within 1 foot of the foundation, versus 81027236, which is approximately 3 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 29 buildings at the IAA encompass an area of 72,191 ft^2. When the area of the foundations (37,641 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 34,550 ft^2, or approximately 0.8 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to barium at the IAA.

Cadmium – Cadmium was detected in 52 out of 90 surface soil samples, with concentrations ranging from 0.06 mg/kg to 15.2 mg/kg. Thirty-six concentrations were above the ESL of 0.36 mg/kg, and twenty-six concentrations were above the background value of 0.69 mg/kg established at the site. However, when the EPC of 2.198 mg/kg was calculated, this value was within the range of background samples detected at the site. Consequently, adverse effects to wildlife exposed to cadmium are unlikely given the similarity of detected concentrations with the range of site background values. This COPEC was further evaluated in the terrestrial food chain model.

Chromium – Chromium was detected in 99 out of 99 surface soil samples, with concentrations ranging from 11.9 mg/kg to 1,920 mg/kg. Seventy-nine of these concentrations were above the ESL of 26 mg/kg, and 13 concentrations were above the background value of 65.3 mg/kg established at the site. As previously discussed, a closer examination of the location of those soil samples with elevated levels of chromium indicates that the concentrations of chromium in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (Figure 5-2). For example, in sample location SS-12 (collected approximately 5 feet from the building foundation) the concentration of chromium is 99.2 mg/kg, compared to 36.8 mg/kg in sample location IASS02 (collected approximately 15 feet away from the foundation), which is below the background value of 65.3 mg/kg established at the site. This trend is repeated in other sample locations (i.e., IATP2A/C, which is located within 1 foot of the foundation, versus 81027236, which is approximately 3 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 29 buildings at the IAA encompass an area of 72,191 ft^2. When the area of the foundations (37,641 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 34,550 ft^2, or approximately 0.8 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to chromium at the IAA.

Cobalt – Cobalt was detected in 97 out of 99 surface soil samples, with concentrations ranging from 0.26 mg/kg to 422 mg/kg. While 36 concentrations were above the ESL of 13 mg/kg, only the maximum concentration was above the range of background samples detected at the site (5.9 mg/kg to 130 mg/kg). When the EPC of 38.29 mg/kg was calculated, this value was below the background value of 72.3 mg/kg established at the site. In addition, the calculated HQ was only slightly above the benchmark value of 1 (HQ=3). Consequently, adverse effects to wildlife exposed to cobalt are unlikely given the similarity of detected concentrations with the site background values and the likely overestimate of potential risks to wildlife presented by the HQ.

Copper – Copper was detected in 99 out of 99 surface soil samples, with concentrations ranging from 9.1 mg/kg to 56,500 mg/kg. Seventy-six concentrations were above the ESL of 28 mg/kg, and 58 concentrations were above the background value of 53.5 mg/kg established at the site. As previously discussed, a closer examination of the location of those soil samples with elevated levels of copper indicates that the concentrations of copper in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (Figure 5-2). For example, in sample location SS-12 (located approximately 5 ft from the building foundation) the concentration of copper is 56,500 mg/kg, compared to 97.2 mg/kg in sample location IASS02 (located approximately 15 feet away from the foundation), which is within the detected range of background values (1.6 mg/kg to 38.7 mg/kg) at the site. This trend is repeated in other sample locations (i.e., IATP2A/C, which is located within 1 foot of the foundation, versus 81027236, which is approximately 3 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 29 buildings at the IAA encompass an area of 72,191 ft^2. When the area of the foundations (37,641 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 34,550 ft^2, or approximately 0.8 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to copper at the IAA. Additionally, copper was further evaluated in the terrestrial food chain model.

Iron – Iron was detected in 99 out of 99 surface soil samples, with concentrations ranging from 9,450 mg/kg to 328,000 mg/kg. While no ESL was available for iron, all but two of these concentrations were within the range of background values (7,250 mg/kg to 67,700 mg/kg) detected at the site. Consequently, adverse effects to wildlife exposed to iron are unlikely given the similarity of detected concentrations with the range of site background values.

Lead – Lead was detected in 99 out of 99 surface soil samples, with concentrations ranging from 6.4 mg/kg to 16,200 mg/kg. All but five of these concentrations were above the ESL of 11 mg/kg, and 28 concentrations were detected outside of the range of background samples (2.1 mg/kg to 256 mg/kg) detected at the site. As previously discussed, a closer examination of the location of those soil samples with elevated levels of lead indicates that the concentrations of lead in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (Figure 5-2). For example, in sample location SS-12 (located approximately 5 ft from the building foundation) the concentration of lead is 563 mg/kg, compared to 49.1 mg/kg in sample location IASS02 (located approximately 15 feet away from the foundation), which is within the detected range of background values (2.1 mg/kg to 256 mg/kg) at the site. This trend is repeated in other sample locations (i.e., IATP2A/C, which is located within 1 foot of the foundation, versus 81027236, which is approximately 3 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 29 buildings at the IAA encompass an area of 72,191 ft^2. When the area of the foundations (37,641 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 34,550 ft^2, or approximately 0.8 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to lead at the IAA. Additionally, lead was further evaluated in the terrestrial food chain model.

<u>Mercury</u> – Mercury was detected in 75 out of 84 surface soil samples, with concentrations ranging from 0.015 mg/kg to 79.5 mg/kg. Twenty-four of these concentrations were above the ESL of 0.1 mg/kg. As previously discussed, a closer examination of the location of those soil samples with elevated levels of mercury indicates that the concentrations of mercury in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (Figure 5-2). For example, in sample location IAA-SS026 (located approximately 5 ft from the building foundation) the concentration of mercury is 1.9 mg/kg, compared to <0.050 mg/kg in sample location IASB15 (located approximately 10 feet away from the foundation), which is below the background value of 0.13 mg/kg established at the site. This trend is repeated in other sample locations (i.e., IATP2A/C, which is located within 1 foot of the foundation, versus 81027236, which is approximately 3 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 29 buildings at the IAA encompass an area of 72,191 ft^2. When the area of the foundations (37,641 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 34,550 ft^2, or approximately 0.8 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to mercury at the IAA.

<u>Zinc</u> – Zinc was detected in 99 out of 99 surface soil samples, with concentrations ranging from 6 mg/kg to 21,800 mg/kg. Seventy-four of these concentrations were greater than the ESL of 46 mg/kg, and forty-one concentrations were above the background value of 202 mg/kg established at

the site. As previously discussed, a closer examination of the location of those soil samples with elevated levels of zinc indicates that the concentrations of zinc in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected further away from the foundation (Figure 5-2). For example, in sample location SS-12 (located approximately 5 ft from the building foundation) the concentration of zinc is 6,460 mg/kg, compared to 88.1 mg/kg in sample location IASS02 (located approximately 15 feet away from the foundation), which is below the background value of 202 mg/kg established at the site. This trend is repeated in other sample locations (i.e., IATP2A/C, which is located within 1 foot of the foundation, versus 81027236, which is approximately 3 feet away from the foundation). The areal extent of the affected soils that are around the perimeter of the 29 buildings at the IAA encompass an area of 72,191 ft^2. When the area of the foundations (37,641 ft^2) is subtracted, the extent of affected soil available for ecological exposure is 34,550 ft^2, or approximately 0.8 acre. Based on these considerations, adverse impacts at the population-level are not considered likely for ecological receptors exposed to zinc at the IAA. Additionally, zinc was further evaluated in the terrestrial food chain model.

Thirty-six COPECs were identified as bioaccumulative and evaluated in the terrestrial food chain model.

5.5.3.2 Sediment

Eleven COPECs in sediment were carried forward into the BERA. When refined EPCs were compared with the ESLs, only one constituent, iron, had a refined HQ greater than 1. In addition, ESLs were not available for three other constituents (barium; beryllium; and vanadium). The BERA results for sediment COPECs at the IAA are presented in Table A.5.ERA-4 and are discussed below:

Inorganics: Four inorganics (barium; beryllium; iron; and vanadium) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1, or an HQ could be calculated because an ESL was not available. These results are discussed below:

Barium – Barium was detected in 4 out of 4 sediment samples, with concentrations ranging from 36.8 mg/kg to 48.9 mg/kg. While no screening value was available for barium and no background sediment data was collected, all of these detected concentrations were below the soil background value of 209 mg/kg established at the site. Consequently, adverse effects to aquatic life exposed to barium are unlikely given the similarity of detected concentrations with the site background value.

Beryllium – Beryllium was detected in 4 out of 4 sediment samples, with concentrations ranging from 0.61 mg/kg to 1.2 mg/kg. While no screening value was available for beryllium and no background sediment data was collected, all of these detected concentrations were within the range of detected soil background values (0.61 mg/kg to 5.4 mg/kg) at the site. Consequently, adverse effects to aquatic life exposed to beryllium are unlikely given the similarity of detected concentrations with the range of site background values.

Iron – Iron was detected in 4 out of 4 sediment samples, with concentrations ranging from 27,900 mg/kg to 32,300 mg/kg. While no ESL was available for iron, and no background sediment data was collected, all of these detected concentrations were below the soil background value of 50,962 mg/kg established at the site. Consequently, adverse effects to aquatic life exposed to iron are unlikely given the similarity of detected concentrations with the soil background value.

Vanadium –Vanadium was detected in 4 out of 4 sediment samples, with concentrations ranging from 50.7 mg/kg to 62.6 mg/kg. While no screening value was available for vanadium and no background sediment data was collected, all of these detected concentrations were within the range of detected soil background values (12.2 mg/kg to 114 mg/kg) at the site. Consequently, adverse effects to aquatic life exposed to vanadium are unlikely given the similarity of detected concentrations with the range of site background values.

Six constituents were also defined as bioaccumulative (arsenic; cadmium; copper; lead; nickel; and zinc) and were evaluated in the aquatic food web model..

5.5.4 Refinement of Assessment and Measurement Endpoints for Bioaccumulative COPECs

Food chain modeling was conducted at the IAA in order to evaluate the potential ecological effects of the bioaccumulative COPEC in soil on the receptors identified in Section 2.4. COPECs identified in soil and sediment were evaluated in the terrestrial and aquatic food chains, respectively.. The results for both the maximum and refined scenarios of the terrestrial and aquatic models are presented in Tables A.5.ERA-5 through A.5.ERA-12

5.5.4.1 Terrestrial Food chain Model

The refined scenario NOAEL and LOAEL HQs for the short-tailed shrew (Tables A.5.ERA-5 and A.5.ERA-6) were less than 1 for all pesticides and for all PAHs except the NOAEL HQ for dibenzo(ah)anthracene and indeno(1,2,3-cd)pyrene .In addition, the the remaining six constituents (Aroclor 1254, Aroclor 1260, cadmium, copper, lead, and zinc) had a NOAEL HQ greater than 1 and/or a LOAEL HQ above 1 as discussed below.

The NOAEL HQs for short-tailed shrew for dibenzo(ah)anthracene and indeno(1,2,3-cd)pyrene were very low (HQ=3 for both COPEC) indicating only a slight risk. Taking into account the conservative nature of the mammalian TRVs applied, it is likely that this risk is overestimated. As previously noted, the soil ESLs applied to PAHs were based on exposures to the masked shrew and maximum concentrations for both these chemicals were well below the reported values. Based on this assessment, risks associated with these two chemicals is unlikely.

Two PCBs, Aroclor 1254 and Aroclor 1260, had NOAEL HQs above 1. Aroclor 1254 had a NOAEL HQ of 7 and a LOAEL HQ of 0.7. However, when looking at the Aroclor 1254 dataset, the maximum concentration was detected at 12 mg/kg, while the next highest concentration was 0.89 mg/kg. If the maximum concentration of 12 mg/kg was excluded, an EPC of 0.23 mg/kg was calculated, which would produce a shrew NOAEL HQ below 1. Aroclor 1260 had a NOAEL HQ of 2 and a LOAEL HQ of 0.2. However, due to the overly conservative criterion of the NOAEL and the low frequency of detection (i.e., 10 % in surface soil), these results indicate that individual shrews (or other insectivorous mammals) exposed to PCBs are not expected to experience adverse effects.

Similarly two inorganics, cadmium and lead, both had NOAEL HQs of 2 and LOAEL HQs of 0.2. As previously discussed, the NOAEL is a very conservative screening criterion, while the LOAEL indicates a concentration above which adverse impacts to individual mammals may occur. In addition, the cadmium EPC of 2.198 mg/kg was within the range of detected concentrations at the site (0.62 mg/kg to 2.5 mg/kg), and the lead EPC of 200 mg/kg was below the established site background value of 202 mg/kg. Based on this information, these results indicate that individual shrews (or other insectivorous mammals) exposed to cadmium and lead are not expected to experience adverse effect.

Refined NOAEL and LOAEL HQs for copper (HQ=8; HQ=6) and zinc (HQ=40; HQ=4) were above 1. As discussed in the BERA above, although there are some soil samples at the IAA with elevated concentrations of both copper and zinc, a closer examination of the location of those samples in relation to the concrete building foundations, and their spatial extent indicates that the concentrations of copper and zinc in samples collected from immediately adjacent to the foundations contain higher concentrations than in samples collected farther away from the foundation (i.e., in general, concentrations decrease with distance from the foundations). The areal extent of the affected soils that are around the perimeter of the 29 buildings (excluding the area of the building foundation itself) at the IAA encompass an area of 34,550 ft^2 or roughly 0.8 acre. This is the extent of affected soil available for ecological exposure. While these elevated levels of copper and zinc may cause localized impacts to individual shrews; overall, the total impact area is less than 1 acre and is unlikely to pose a significant adverse ecological impact to ecological receptors at the population-level.

The refined scenario NOAEL and LOAEL HQs for the American robin were presented in Tables A.5.ERA-7 and A.5.ERA-8. Here, the NOAEL and LOAEL HQs for benzo(a)pyrene, Aroclor 1254, Aroclor 1260, and cadmium, while the remaining three constituents (copper, lead, and zinc) a NOAEL HQ greater than 1 and/or a LOAEL HQ above 1 as discussed below.

Lead and zinc both had NOAEL HQs above 1. Lead had a NOAEL HQ of 8 and a LOAEL HQ of 0.8. Zinc had a NOAEL HQ of 10 and a LOAEL HQ of 1. Copper had a NOAEL HQ of 6 and a LOAEL HQ of 5. As previously discussed, the NOAEL is a very conservative screening criterion, while the LOAEL indicates a concentration above which adverse impacts to individual mammals may occur. In addition, although there are some soil samples at the IAA with elevated concentrations of both copper, lead, and zinc, the areal extent of ecological exposure to the affected soils that are around the perimeter of the 29 buildings (excluding the area of the building foundation itself) at the IAA encompass an area of less than 1 acre and is unlikely to pose a significant adverse ecological impact to ecological receptors at the population-level. While these elevated levels of copper, lead, and zinc may cause localized impacts to individual robins; overall, the total affected area is unlikely to pose a significant adverse ecological impact to ecological receptors at the population-level.

Based on the overall analysis of terrestrial food chain modeling HQs and consideration of the limited spatial extent of affected soils, adverse effects are not expected for short-tailed shrews (and other insectivorous mammals) and American robins (and other insectivorous birds) populations exposed to bioaccumulative COPECs in soil at the IAA.

5.5.4.2 Aquatic Food Chain Model

The results of the aquatic food chain model indicate that all HQs were below 1 for both great blue heron and mink (Tables A.5.ERA-9 through A.5.ERA-12) with the exception of the zinc NOAEL HQ for mink which was 2. Given the very low exceedance and the conservatism inherent in the assessment, it was concluded that the area was unlikely to pose a significant adverse ecological impact to ecological receptors at the population-level.

5.5.5 Ecological Risk Summary

Screening-level and baseline risk assessments were completed for the IAA. After the SLERA, 53 constituents were selected as COPECs in surface soil, and 11 constituents were selected as COPECs in sediment because the HQs were greater than 1, the chemical was bioaccumulative or an HQ could not be calculated because an ESL was not available. After the BERA, all constituents in surface soil, and 10 constituents in sediment were retained. Food chain modeling was evaluated for all those constituents identified as bioaccumulative.

Tables A.5.ERA-13 and A.5.ERA-14 summarize the results of the terrestrial and aquatic food chain models, respectively. Based on these results, in conjunction with the information on the limited spatial distribution and extent of these constituents in surface soil and sediment, , the potential for population-level effects is low.

Based on the overall analysis of the ERA for the IAA, the results indicate that adverse population-level effects are not expected for wildlife at the site.

5.6 IAA Summary and Conclusions

An HHRA was conducted at the IAA to evaluate potential exposures to humans associated with site constituents. Site worker exposures to surface soil and sediment were evaluated under current and future land-use conditions; and construction worker, adult resident, and child resident exposures to total soil and sediment were evaluated under future land-use conditions.

The soil and sediment COPCs were evaluated for direct contact. VOCs identified as COPCs in the IAA were also evaluated for inhalation via vapor migration into buildings.

Igniter Assembly Area

Two VOCs, 3-octanone and d-limonene, do not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area.

A current or future site worker could be present at the IAA area, and could be exposed to surface soil or sediment. The total cumulative ELCR for site workers exposed to surface soil and sediment at the IAA is 1×10^{-4}, which is equal to the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 1, which is equal to the benchmark of 1; however, all segregated hazards were less than or equal to 1. Lead was also evaluated as a COPC, although the results are reported differently than those for the other COPCs. The predicted worker blood lead levels were below the benchmark and the predicted fetal lead level was equal to the benchmark.

A hypothetical future construction worker could be present at the IAA area, and could be exposed to combined surface and subsurface soil. The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the IAA was 6×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 3, which is above the benchmark of 1 due mostly to copper. Hazards are less than or equal to 1 when segregated by target organ. The predicted worker blood lead levels were below the benchmark and the predicted fetal lead level was equal to the benchmark.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil and sediment at the IAA is 5×10^{-4}, which is above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The primary contributor to risk estimates is 2,4-dinitrotoluene in soil. Other contributors to the excess lifetime cancer risks were benzo(a)pyrene, PCBs, and arsenic.

The total cumulative HI for hypothetical future adult residents is 1, which is equal to the benchmark. When the hazards were segregated by target organ or critical effect, all of the HIs were less than 1. The predicted adult resident blood lead levels were below the benchmark of 10 µg/dl, and the predicted fetal lead level was slightly greater than the benchmark.

The total cumulative HI for hypothetical future child residents is 13, which is above the benchmark of 1. When the HI was is segregated by target site and critical effects, hazards were greater than the benchmark of 1 due to the presence of Aroclor 1254, cobalt, and 2,4-dinitrotoluene. The predicted blood lead levels were all below the benchmark.

2,4-Dinitrotoluene was detected in two of thirty samples with the two detections collected from two depths at sampling location 504360 during the December 1997 sampling event. No other detections of this constituent were confirmed during the subsequent sampling events. Aroclor 1254 was detected in 18 of 61 surface soil samples with detected concentrations ranging from 0.03 to 12 mg/kg. Only six samples exceeded the RSL of 0.22 mg/kg for residential exposure and three samples exceeded the RSL of 0.74 mg/kg for industrial exposure. Finally, only the maximum concentration of cobalt (422 mg/kg) fell outside of the background concentration range of 5.9 mg/kg to 130 mg/kg.

Removal of the walls and roofs of the IAA buildings has exposed conductive flooring material to weather, causing it to degrade and wash onto the surrounding soils. Based on the results of activity-based air sampling conducted in soils surrounding some of those buildings, it appears that the presence of asbestos may present a potential risk for current and future site workers and hypothetical future residents.

A SLERA and BERA were completed for the IAA, to evaluate surface soil and sediment for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial food chain models indicate that while some of the NOAEL and LOAEL HQs were greater than 1, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, effects of these COPECs at the population-level are unlikely at the IAA.

.

6. Rail Yard (RY)

6.1 Site Description and History

The RY encompasses an open area approximately 3,200 ft long by 350 ft wide (approximately 39 acres) in the central portion of the RFAAP-NRU. The RY was used for loading and unloading rail cars and the temporary storage of rail cars. The area contained three parallel sets of tracks and several spurs so that cars could be rearranged. Four of the spurs at the north end of the site were surrounded by earthen berms. Three open transfer platforms and one bermed transfer platform are located along the southernmost track for loading and unloading the trains. A decommissioned sewer line runs southwest from a building foundation to a branch of the RFAAP-NRU sewer system that is no longer in use.

6.2 Physical Setting

The RY area is relatively flat at an elevation of approximately 2,100 ft amsl. The area is very open with much of the site being covered with asphalt roadways, gravel, and grass groundcover. Surface water runoff from the RY is directed to two tributaries to the unnamed creek that flows through the southwest portion of the RFAAP-NRU. Engineered drainage control ditches channel runoff in the areas between the tracks, ultimately draining into one of the two tributaries.

6.3 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. Risk assessment datasets for soil, sediment, and surface water for the RY were prepared then summarized and statistically analyzed. Risk assessment datasets summaries highlighting: the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPC are presented in Tables A.6.Data-1 through A.6.Data-5.

6.4 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with constituents detected in soil, sediment and surface water samples collected at the RY. The risk assessment approach follows the Radford Army Ammunition Plant Final Master Work Plan (URS 2003).

The risk assessment approach is based on Virginia and USEPA guidance for risk assessments (VDEQ 2008; USEPA 2004a- 2000a- 1997a- 1992- 1991a- 1989). This section summarizes the occurrence of constituents in each medium and identifies COPCs at the RY for the human health risk assessment; identifies the potential human exposure scenarios relevant to the RY; and presents the estimated human health risks associated with the identified COPCs and the relevant human exposure scenarios at the RY. Methodologies for data summary and selection of COPCs, exposure assessment, and toxicity assessment for the HHRA were presented in Section 2.3.

6.4.1 Selection of Constituents of Potential Concern

This section discusses the selection of COPCs for each medium.

6.4.1.1 Surface Soil

Surface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.6.HHRA-1 presents the selection of surface soil COPCs for the HHRA. As summarized in Table A.6.HHRA-1, 14 constituents were identified as COPCs in surface soil as follows:

Five VOCs (2-butanone; 3-octanone; acetone; ethanol; and methylene chloride) were detected in surface soil. 2-Butanone, acetone, and methylene chloride were detected at concentrations below their USEPA (2009a) residential soil RSL values. USEPA (2009a) residential soil RSL values were not available for 3-octanone or ethanol. As a result, both 3-octanone and ethanol were identified as COPCs for surface soil.

Nine SVOCs (2,4-dinitrotoluene; 2,6-dinitrotoluene; benzoic acid; bis[2-ethylhexyl]phthalate; carbazole; dibenzofuran; diethylphthalate; di-n-butylphthalate; and pentachlorophenol) were detected in surface soil. Only pentachlorophenol was detected at a maximum concentration greater than the USEPA (2009a) residential soil RSL value. In addition, a USEPA (2009a) residential soil RSL value was not available for carbazole; as a result, these two constituent was identified as COPCs for surface soil.

One explosive-related compound, 4-amino-2,6-dinitrotoluene, was detected in surface soil. This constituent, which is a degradation product of 2,4,6-trinitrotoluene (TNT) (Hovatter et al. 1997) was detected at concentrations below the USEPA (2009a) residential soil RSL value, and as a result, was not identified as a COPC for surface soil.

Six pesticides (4,4'-DDE; alpha-BHC; beta-BHC; alpha-chlordane; dieldrin; and endrin aldehyde) were detected in surface soil. Only dieldrin was detected at concentrations above the USEPA (2009a) residential soil RSL value and was identified as a COPC for surface soil.

Seventeen PAHs (2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in surface soil. Four of these detected constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; and dibenzo[a,h]anthracene) were greater than the USEPA (2009a) residential soil RSL values and were identified as COPCs for surface soil.

One PCB, Aroclor 1254, was detected in surface soil. This constituent was detected at concentrations above the USEPA (2009a) residential soil RSL value and was identified as a COPC for surface soil

Twenty-two inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; sodium; thallium; vanadium; and zinc) were detected in surface soil. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Eight of these constituents (aluminum; arsenic; barium; cobalt; iron; manganese; thallium; and vanadium) were greater than the USEPA (2009a) residential soil RSL values. However, iron, manganese, thallium, and vanadium were all detected below the background concentrations. As a result, only aluminum, arsenic, barium, and cobalt were identified as COPCs for surface soil.

6.4.1.2 Combined Surface and Subsurface Soil

Combined surface and subsurface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.6.HHRA-2 presents the selection of combined surface and subsurface soil COPCs for the HHRA. As summarized in Table A.6.HHRA-2, 14 constituents were identified as COPCs in combined surface and subsurface soil as follows:

Five VOCs (2-butanone; 3-octanone; acetone; ethanol; and methylene chloride) were detected in combined surface and subsurface soil. 2-Butanone, acetone, and methylene chloride were detected below their USEPA (2009a) residential soil RSL values. USEPA (2009a) residential soil RSL values were not available for 3-octanone or ethanol. As a result, only 3-octanone and ethanol were identified as COPCs for combined surface and subsurface soil.

Ten SVOCs (2,4-dinitrotoluene; 2,6-dinitrotoluene; benzoic acid; bis[2-ethylhexyl]phthalate; butylbenzylphthalate; carbazole; dibenzofuran; diethylphthalate; di-n-butylphthalate; and pentachlorophenol) were detected in combined surface and subsurface soil. Only pentachlorophenol was detected at concentrations that were greater than the USEPA (2009a) residential soil RSL value. In addition, a USEPA (2009a) residential soil RSL value was not available for carbazole. As a result, both of these constituents were identified as COPCs for combined surface and subsurface soil.

One explosive, 4-amino-2,6-dinitrotoluene, was detected in combined surface and subsurface soil. This constituent was detected at concentrations below the USEPA (2009a) residential soil RSL value and was not identified as a COPC in combined surface and subsurface soil.

Six pesticides (4,4'-DDE; alpha-BHC; beta-BHC; alpha-chlordane; dieldrin; and endrin aldehyde) were detected in combined surface and subsurface soil. Only dieldrin was detected at concentrations above the USEPA (2009a) residential soil RSL value and was identified as a COPC for combined surface and subsurface soil.

Seventeen PAHs (2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in combined surface and subsurface soil. Four of these detected constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; and dibenzo[a,h]anthracene) were detected at concentrations greater than the USEPA (2009a) residential soil RSL values and were identified as COPCs for combined surface and subsurface soil.

One PCB, Aroclor 1254, was detected in combined surface and subsurface soil. This constituent was detected above the USEPA (2009a) residential soil RSL value and was identified as a COPC for combined surface and subsurface soil

Twenty-two inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; sodium; thallium; vanadium; and zinc) were detected in combined surface and subsurface soil. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Eight of these constituents (aluminum; arsenic; barium; cobalt; iron; manganese; thallium; and vanadium) were greater than the USEPA (2009a) residential soil RSL values. However, iron, manganese, thallium, and vanadium were all detected below the background concentrations; as a result, only aluminum, arsenic, barium, and cobalt were identified as COPCs for combined surface and subsurface soil.

6.4.1.3 Sediment

Sediment COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.6.HHRA-3 presents the selection of sediment COPCs for the HHRA. As summarized in Table 6-18, 12 constituents were identified as COPCs in sediment as follows:

Four VOCs (2-butanone; acetone; carbon disulfide; and methylene chloride) were detected in sediment. All of these constituents were below the USEPA (2009a) residential soil RSL values and were not identified as COPCs for sediment.

Four SVOCs (4-methylphenol; benzoic acid; bis[2-ethylhexyl]phthalate; and di-n-butylphthalate) were detected in sediment. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values.

Two explosives (nitroglycerine and pentaerythritol tetranitrate) were detected in sediment. Nitroglycerine was detected at concentrations below the USEPA (2009a) residential soil RSL value. No RSL was available for pentaerythritol tetranitrate. As a result, only pentaerythritol tetranitrate was identified as a COPC for sediment.

Seven herbicides (2,4,5-T; 2,4,5-TP; 2,4-D; dalapon; dicamba; dichlorprop; and MCPP) were detected in sediment. All detected herbicides were detected at concentrations below the USEPA (2009a) residential soil RSL values with the exception of dichlorprop, which did not have a value available. As a result, dichlorprop was the only herbicide identified as a COPC for sediment.

Sixteen pesticides (4,4’-DDD; 4,4’-DDE; 4,4’-DDT; alpha-BHC; delta-BHC; gamma-BHC; alpha-chlordane; gamma-chlordane; dieldrin; endosulfan II; endrin; endrin aldehyde; endrin ketone; heptachlor; heptachlor epoxide; and methoxyclor) were detected in sediment. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values.

Seventeen PAHs (2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in sediment. Four of these detected constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; and dibenzo[a,h]anthracene) were present at concentrations greater than the USEPA (2009a) residential soil RSL values and were identified as COPCs for sediment.

Twenty-two inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; sodium; thallium; vanadium; and zinc) were detected in sediment. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Six of these constituents (aluminum; arsenic; cobalt; iron; manganese; and vanadium) were greater than the USEPA (2009a) residential soil RSL values. Consequently, only aluminum, arsenic, cobalt, iron, manganese, and vanadium were identified as COPCs for sediment.

6.4.1.4 Surface Water

Surface water COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for tap water. Table A.6.HHRA-4 presents the selection of surface water COPCs for the HHRA. As summarized in Table A.6.HHRA-4, nine constituents were identified as COPCs in surface water as follows:

Two VOCs (carbon disulfide and chloroform) were detected in surface water. Of these two constituents, only chloroform was detected above the USEPA (2009a) tap water RSL values and was identified as a COPC for surface water.

Five SVOCs (benzoic acid; bis[2-ethylhexyl]phthalate; butylbenzylphthalate; diethylphthalate; and di-n-buthylphthalate) were detected in surface water. Of these detected constituents, only bis(2-ethylhexyl)phthalate was detected above the USEPA (2009a) tap water RSL value and was identified as a COPC for surface water.

One explosive (nitroglycerine) and two explosive degradation products (m-nitrotoluene and nitrobenzene) were detected in surface water. Only one of these three constituents, nitroglycerine, was detected at concentrations above the USEPA (2009a) tap water RSL value and was identified as a COPC for surface water.

Five herbicides (2,4,5-TP; 2,4-D; 2,4-DB; MCPA; and MCPP) were detected in surface water. Only MCPA and MCPP were detected at concentrations above the USEPA (2009a) tap water RSL values and were identified as COPCs for surface water.

Six pesticides (4,4'-DDT; delta-BHC; dieldrin; endosulfan sulfate; endrin aldehyde; and endrin ketone) were detected in surface water. Only dieldrin was detected at concentrations above the USEPA (2009a) tap water RSL value and was identified as a COPC for surface water.

Three PAHs (2-methylnaphthalene; naphthalene; and phenanthrene) were detected in surface water. All three constituents were detected at concentrations below the USEPA (2009a) tap water RSL values and were not identified as COPCs for surface water.

Sixteen inorganics (aluminum; antimony; barium; cadmium; calcium; chromium; copper; iron; lead; magnesium; manganese; potassium; selenium; silver; sodium; and zinc) were detected in surface water. Three of these detected constituents (iron; lead; and manganese) were detected above the USEPA (2009a) tap water RSL values. Four (calcium; magnesium; potassium; and sodium) were identified as essential nutrients. As a result, only iron, lead, and manganese were identified as COPCs for surface water.

6.4.2 Summary of Selected Constituents of Potential Concern

Fifteen constituents were selected as COPCs in surface soil and combined surface and subsurface soil at the RY, including two VOCs (3-octanone and ethanol), two SVOCs (carbazole and pentachlorophenol), four PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; and dibenzo[a,h]anthracene), one pesticide (dieldrin), one PCB (Aroclor 1254), and five inorganics (aluminum; arsenic; barium; cobalt; and lead).

Twelve constituents were selected as COPCs in sediment at the RY, including four PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; and dibenzo[a,h]anthracene), one herbicide (dichlorprop), one explosive (pentaerythritol tetranitrate), and six inorganics (aluminum; arsenic; cobalt; iron; manganese; and vanadium).

Nine constituents were selected as COPCs in surface water at the RY, including one VOC (chloroform), one SVOC (bis[2-ethylhexyl]phthalate, two herbicides (MCPA and

MCPP), one explosive (nitroglycerine), and four inorganics (cadmium; iron; lead; and manganese).

6.4.3 Determination of Exposure Point Concentrations

Fifteen constituents were selected as COPCs in both surface soil and combined surface and subsurface soil, twelve constituents were selected as COPCs in sediment, and ten constituents were selected as COPCs in surface water because the maximum detected concentrations were greater than the corresponding USEPA (2009a) RSL or no RSL was available. The distribution testing and UCL calculations were performed as described in Section 2.2.6.1, and the EPCs for these COPCs are summarized in Table A.6.HHRA-5.

6.4.4 Human Health Risk Characterization

The physical and chemical properties and toxicity values used to evaluate excess lifetime cancer risks and non-cancer hazards are presented in Tables A.2-3 through A.2-9. The exposure assumptions used to evaluate potentially exposed receptors are presented in Table A.2-10. The equations used in the risk characterization calculations are presented in Tables A.2-11 through A.2-15.

Exposure to the soil, sediment, and surface water COPCs were evaluated for direct contact. VOCs identified as COPCs in the RY were also evaluated for inhalation via vapor migration into buildings. Two VOCs, 3-octanone and ethanol, were identified as soil COPCs at the RY. These COPCs do not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area.

The excess lifetime cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the RY are summarized in the table and subsections below.

6.4.4.1 Site Worker

A current or future site worker could be present at the RY area, and could be exposed to surface soil, sediment, or surface water. The ELCR and non-cancer hazard index for site worker exposure to each medium are presented in Tables A.6.HHRA-6 through A.6.HHRA-8 for surface water, and are summarized in Table A.6.HHRA-16. The ELCRs for surface soil, sediment, and surface water are all below or within the USEPA target risk range, and the HIs for each medium are all below the benchmark value of 1.

The total cumulative ELCR for site workers exposed to surface soil, sediment, and surface water at the RY is 1×10^{-4}, which is equal to the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.4, which is less than the benchmark of 1.

6.4.4.2 Hypothetical Future Construction Worker

A hypothetical future construction worker could be present at the RY area, and could be exposed to combined surface and subsurface soil. The ELCR and non-cancer hazard index for hypothetical future construction worker exposure to soil are presented Table A.6.HHRA-9, and are summarized in Table A.6.HHRA-16.

The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the RY was 5×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 0.7, which is less than the benchmark of 1.

6.4.4.3 Hypothetical Future Residents

A hypothetical future adult or child resident could be present at the RY area, and could be exposed to combined surface and subsurface soil, sediment, or surface water. The ELCR and non-cancer hazard index for hypothetical future adult, child, or aggregate resident exposure to each medium are presented in Tables A.6.HHRA-10 through A.6.HHRA-15, and are summarized in Table A.6.HHRA-16.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water at the RY is 3×10^{-4}, which is slightly above the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The primary risk driver is pentachlorophenol in soil.

The total cumulative HI for hypothetical future adult residents is 0.6, which is less than the benchmark of 1.

The total cumulative HI for hypothetical future child residents is 3, which is greater than the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were only above the benchmark of 1 in the eyes, nails, hair, and skin. The primary contributor to the non-cancer hazard above 1 is cobalt.

6.4.5 Human Health Risk Summary

Tables A.6.HHRA-16 summarizes the calculated cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the RY. As shown in the table below, the total ELCR values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below or within the USEPA target risk range of 10^{-6} to 10^{-4} for cancer risk, with the exception of hypothetical future residential exposure to combined surface and subsurface soil.

Summary of calculated ELCRs and HIs for Receptor Exposure Scenarios

RECEPTOR/ EXPOSURE MEDIUM – SCENARIO	Total ELCR	HI
Site Worker

TOTAL SITE RISKS (Aggregate Resident):	**3E-04**	

The potential risk to the hypothetical future resident is due to the presence of pentachlorophenol (PCP). PCP was detected at a concentration greater than the industrial RSL (9 mg/kg) in one surface soil sample [TR-02C (830 mg/kg)] which was collected in 1998 at a former pole-mounted transformer location. The concentration of PCP in a duplicate surface soil sample collected at this location (TR-02A) was only

0.11mg/kg. A total of 33 soil samples (20 surface soil samples and 13 subsurface soil samples) collected during subsequent investigations at the Rail Yard were analyzed for PCP. PCP was not detected in any of these samples, nor was PCP detected in any surface water or sediment samples at the Rail Yard. As PCP is known to have been used as a wood preservative for utility poles, the single elevated detection of PCP at sample location TR-02C has been linked to the former utility pole at this sample location. The observation that PCP was not detected at elevated levels in the duplicate sample at this location, or in any other soil samples at the site, indicates that the elevated detection was limited to the area in the immediate vicinity of the utility pole.

The risk assessment was based on the maximum detected concentration and thus likely overestimates potential exposures. Without pentachlorophenol, the ELCR would be 3×10^{-5} which is within the USEPA target cancer risk range.

The total HI values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below the benchmark of 1 for non-cancer hazard, with the exception of hypothetical future child resident exposure to combined surface and subsurface soil. The risk driver for non-cancer hazard is cobalt. The maximum cobalt concentration of 74.9 mg/kg is only slightly greater than the background concentration of 72.3 mg/kg and is well within the range of background levels. Therefore, it is likely that cobalt is present due to naturally occurring sources rather than due to activities at the RY.

The results of the human health risk assessment indicate that use of the RY for residential or industrial uses should not result in unacceptable risks to potential receptors.

6.5 Ecological Risk Assessment

The purpose of the ERA is to evaluate whether ecological receptors may be adversely impacted by exposure to site-related constituents detected in surface soil, sediment, and surface water at the RY. The ERA approach is based on the Master Work Plan (URS 2003) in compliance with CERCLA/SARA. The ERA was conducted in a manner consistent with Virginia policy USEPA guidance for ecological risk assessment (USEPA 2001a; 2000b; 1997c). In accordance with USEPA guidance, the ERA for the RY commenced with a SLERA and then concluded with BERA (USEPA 1997c).

This section summarizes the occurrence of constituents in each medium and identifies COPECs at the RY for the ecological risk assessment; identifies the potential ecological exposure scenarios relevant to the RY; and presents the estimated ecological risks associated with the identified COPECs and the relevant ecological exposure scenarios at the RY. Methodologies for data summary and selection of COPECs, exposure assessment, and toxicity assessment for the ERA were presented in Section 2.4.

6.5.1 Selection of Constituents of Potential Ecological Concern

This section discusses the selection of COPECs for each medium. Risks to ecological receptors are calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the hazard quotient (HQ), is a highly conservative surrogate for the assessment endpoints identified in Section 2.4. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse ecological effects are unlikely (USEPA 1997c). HQs greater than 1 indicate that further evaluation is warranted. Therefore, the constituents with HQs greater than 1 are carried forward as COPECs into the BERA. Because the majority of the ESLs measure direct exposures and do not take into account exposures to upper trophic level species, chemicals identified as bioaccumulative were also carried forward as COPECs regardless of whether or not the associated HQ was greater than 1. Finally, as previously described, concentrations of inorganic constituents in soil were compared to soil background concentrations; those with concentrations below background were not considered as COPEC. The COPEC selection process for the RY are summarized in the subsections below.

6.5.1.1 Surface Soil

Surface soil COPECs were selected by comparing the analytical data with USEPA (2008c) EcoSSLs, USEPA (2003e) Region 5 ESLs, and ORNL values (Efroymson et al. 1997a,b) for surface soil. Table A.6.ERA-1 presents the selection of surface soil COPECs for the ERA. As summarized in Table A.6.ERA-1, 42 constituents were identified as COPECs in surface soil as follows:

Five VOCs (2-butanone; 3-octanone; acetone; ethanol; and methylene chloride) were detected in surface soil. HQs were less than or equal to 1 for 2-butanone, acetone, and methylene chloride; however, ESLs were not available for 3-octanone or ethanol and an HQ could not be calculated for these constituents. As a result, both 3-octanone and ethanol were identified as COPECs in surface soil.

Nine SVOCs (2,4-dinitrotoluene; 2,6-dinitrotoluene; benzoic acid; bis[2-ethylhexyl]phthalate; carbazole; dibenzofuran; diethylphthalate; di-n-butylphthalate; and pentachlorophenol) were detected in surface soil. Four of these constituents (2,6-

dinitrotoluene; bis[2-ethylhexyl]phthalate; di-n-butylphthalate; and pentachlorophenol) had HQs greater than 1. In addition, ESLs were not available for benzoic acid, carbazole, or dibenzofuran and so HQs could not be calculated for these constituents. As a result, 2,6-dinitrotoluene, benzoic acid, bis(2-ethylhexyl)phthalate, carbazole, dibenzofuran, di-n-butylphthalate, and pentachlorophenol were identified as COPECs for surface soil.

One explosive, 4-amino-2,6-dinitrotoluene, was detected in surface soil. This constituent had an HQ greater than 1, and as a result, was identified as a COPEC for surface soil.

Six pesticides (4,4'-DDE; alpha-BHC; beta-BHC; alpha-chlordane; dieldrin; and endrin aldehyde) were detected in surface soil. Only three of these constituents (4,4'-DDE; dieldrin; and endrin aldehyde) had an HQ greater than 1, however, the other three were identified as bioacuumulative, therefore, all six were identified as COPECs for surface soil.

Seventeen PAHs (2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in surface soil. All of these detected constituents had HQs less than or equal to 1 however, all but 2-methylnapthalene and naphthalene were identified as bioaccumulative and therefore identified as COPEC.

One PCB, Aroclor 1254, was detected in surface soil. This constituent did not have an ESL and is considered bioaccumulative; as a result, Aroclor 1254 was identified as a COPEC for surface soil

Twenty-two inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; sodium; thallium; vanadium; and zinc) were detected in surface soil. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Fourteen of these constituents (aluminum, antimony; barium; cadmium; chromium; cobalt; copper; lead; manganese; mercury; selenium; thallium; vanadium; and zinc) had an HQ greater than 1, and one constituent (iron) did not have an ESL available and so an HQ could not be calculated. However, six constituents (chromium; iron; manganese; nickel, thallium; and vanadium) were detected below the background concentrations. As a result, aluminum, antimony, arsenic, barium, cadmium, cobalt, copper, lead, mercury, selenium, and zinc were identified as COPECs for surface soil.

6.5.1.2 Sediment

Sediment COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Sediment Screening Levels; ORNL values (Jones et al. 1997); and USEPA (2003e) Region 5 Ecological Screening Levels for sediment. As summarized in Table A.6.ERA-2, 54 constituents were identified as COPECs in sediment as follows:

Four VOCs (2-butanone; acetone; carbon disulfide; and methylene chloride) were detected in sediment. Three of these constituents (2-butanone; acetone; and carbon disulfide) had an HQ greater than 1 and were identified as COPECs in sediment.

Four SVOCs (4-methylphenol; benzoic acid; bis[2-ethylhexyl]phthalate; and di-n-butylphthalate) were detected in sediment. Only one of these constituents, bis(2-ethylhexyl)phthalate, had an HQ greater than 1 and was identified as a COPEC in sediment.

Two explosives (nitroglycerine and pentaerythritol tetranitrate) were detected in sediment. Neither of these constituents had an ESL available and so HQs could not be calculated. As a result, both nitroglycerine and pentaerythritol tetranitrate were identified as COPECs for sediment.

Seven herbicides (2,4,5-T; 2,4,5-TP; 2,4-D; dalapon; dicamba; dichlorprop; and MCPP) were detected in sediment. 2,4,5-T, 2,4,5-TP, and 2,4-D had an HQ less than or equal to 1. However, dalapon, dicamba, dichlorprop, and MCPP did not have ESLs and so an HQ could not be calculated for these constituents. As a result, dalapon, dicamba, dichlorprop, and MCPP were identified as COPECs for sediment.

Sixteen pesticides (4,4'-DDD; 4,4'-DDE; 4,4'-DDT; alpha-BHC; delta-BHC; gamma-BHC; alpha-chlordane; gamma-chlordane; dieldrin; endosulfan II; endrin; endrin aldehyde; endrin ketone; heptachlor; heptachlor epoxide; and methoxyclor) were detected in sediment. Only six of these detected constituents (4,4-DDE; alpha-chlordane; gamma-chlordane; dieldrin; endrin; and heptachlor epoxide) had an HQ greater than 1, however, all of the pesticides except endrin aldehyde and endrin ketone were identified as bioaccumulative and as a result, were identified as COPECs for sediment.

Seventeen PAHs (2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in sediment. Seven of these detected constituents (2-methylnaphthalene; acenaphthene; acenaphthylene; benzo[a]anthracene; indeno[1,2,3-cd]pyrene; phenanthrene; and pyrene) had an HQ greater than 1 and all of the remaining PAHs except naphthalene were identified as bioaccumulative, and as a result, were identified as COPECs for sediment.

Twenty-two inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; sodium; thallium; vanadium; and zinc) were detected in sediment. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Four of these constituents (chromium; copper; iron; and manganese) had an HQ greater than 1, and four constituents (barium; beryllium; thallium; and vanadium) did not have ESLs so an HQ could not be calculated. In addition, six inorganics (arsenic; cadmium; lead; nickel; selenium; and zinc) were identified as bioaccumulative. Consequently, arsenic, cadmium, lead, nickel, selenium, zinc, barium, beryllium, chromium; copper; iron; manganese; thallium, and vanadium were identified as COPECs for sediment.

6.5.1.3 Surface Water

Surface water COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Surface Water Screening Levels; ORNL values (Suter and Tsao 1996); USEPA (2003e) Region 5 Ecological Screening Levels; and USEPA (2008e) Ambient Water Quality Criteria for surface water. As summarized in Table A.6.ERA-3, 17 constituents were identified as COPECs in surface water as follows:

Two VOCs (carbon disulfide and chloroform) were detected in surface water. Both of these constituents had an HQ less than or equal to 1 and were not identified as COPECs for surface water.

Five SVOCs (benzoic acid; bis[2-ethylhexyl]phthalate; butylbenzylphthalate; diethylphthalate; and di-n-buthylphthalate) were detected in surface water. All five of these detected constituents had an HQ less than or equal to 1, and as a result, were not identified as COPECs for surface water.

Three explosives (m-nitrotoluene; nitrobenzene; and nitroglycerine) were detected in surface water. All three of these detected constituents had an HQ less than or equal to 1, and as a result, were not identified as COPECs for surface water.

Five herbicides (2,4,5-TP; 2,4-D; 2,4-DB; MCPA; and MCPP) were detected in surface water. Both 2,4,5-TP and 2,4-D had an HQ less than or equal to 1. However, 2,4-DB, MCPA, and MCPP did not have ESLs and so an HQ could not be calculated for these constituents. As a result, 2,4-DB, MCPA, and MCPP were identified as COPECs for surface water.

Six pesticides (4,4'-DDT; delta-BHC; dieldrin; endosulfan sulfate; endrin aldehyde; and endrin ketone) were detected in surface water. One of these detected constituents, 4,4'-DDT, had an HQ greater than 1 and two (delta-BHC and dieldrin) were identified as bioaccumulative. These three chemicals were identified as COPEC for surface water.

Three PAHs (2-methylnaphthalene; naphthalene; and phenanthrene) were detected in surface water. All three of these detected constituents had an HQ less than or equal to 1, however phenanthrene was identified as bioaccumulative and therefore considered a COPEC for surface water.

Sixteen inorganics (aluminum; antimony; barium; cadmium; calcium; chromium; copper; iron; lead; magnesium; manganese; potassium; selenium; silver; sodium; and zinc) were detected in surface water. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Seven of these detected constituents (aluminum; barium; copper; iron; lead; silver; and zinc) had an HQ greater than 1. In addition three chemicals were identified as bioaccumulative. As a result, aluminum, barium, cadmium, chromium, copper, iron, lead, selenium, silver, and zinc were identified as COPECs for surface water.

One spring sample (RY_SPRING00Y) was also evaluated for surface water COPECs by comparing the analytical data with background spring data as well as ESLs. As shown in the table below, two PAHs and nine inorganics were detected in the spring sample. Four of the inorganics are vital electrolytes and/or essential nutrients (calcium, magnesium, potassium, and sodium) and therefore were identified as non-toxic and not evaluated further. Only two of the inorganics, aluminum and iron, were detected above the background concentrations or were above the corresponding ESL as discussed below.

Aluminum and iron were both detected above the ESL and the background spring sample concentrations. While the detected concentration of aluminum was above the ESL, the ESL used is from USEPA (2008c) Region 3 and is based on a water quality criterion protective of salmonids (i.e., coldwater habitat species of fish such as trout and salmon) which is likely overly conservative for the type of warmwater habitat (and associated aquatic species) that is prevalent in this locale. When an alternative screening value for aluminum of 0.46 mg/L from Sample et al. 1996 was used, an HQ of less than 1 was calculated. This alternative screening value is based on the lowest chronic value for aquatic life, and is considered to be a more representative screening value for aluminum at the RY than the Region 3 ESL.

For iron, although the detected concentration was above the ESL, the spring water sample was slightly turbid (22 NTUs – see Table 10-2) and the sample was not filtered; as such the results represent total iron. Samples collected from other groundwater sources (i.e., monitoring wells) at the RFAAP-NRU indicated the concentrations of iron and other inorganics decrease significantly when filtered samples were collected. Therefore, it is not known what portion, if any, of the iron is in the dissolved (i.e., filtered) form. It is possible that even though the total iron concentrations exceed the ESL, the dissolved (and therefore bioavailable) iron concentrations may in actuality not exceed the ESL. Based on these considerations, adverse effects to aquatic life potentially exposed to inorganics at the RY are unlikely.

6.5.2 Summary of Selected Constituents of Potential Ecological Concern

Fourty-two constituents were selected as COPECs in surface soil, fifty-four constituents were selected as COPECs in sediment, and seventeen constituents were selected as COPECs in surface water because the HQs were greater than 1 or an HQ could not be calculated because an ESL was not available.

6.5.3 Refinement of Risk Calculations for Direct Contact COPECs

The list of COPECs identified in the BERA was reevaluated by calculating refined HQs. The refined HQs were calculated for the COPECs identified in the SLERA using refined EPCs. Constituents identified as COPECs in the BERA that were bioaccumulative were carried forward into food chain models. The results of the recalculation of the HQs for the RY are summarized in the subsections below.

6.5.3.1 Surface Soil

Fourty-two COPECs in surface soil were carried forward into the BERA. When refined EPCs were compared with the ESLs, 10 constituents (2,6-dinitrotoluene; pentachlorophenol; 4,4'-DDE; dieldrin; endrin aldehyde; cobalt; lead; selenium; and zinc) had a refined HQ greater than 1. In addition, ESLs were not available for seven other constituents (3-octanone; ethanol; benzoic acid; carbazole; dibenzofuran, Aroclor 1254; and lead). The BERA results for surface soil COPECs at the RY are presented in Table A.6.ERA-4 and are discussed below:

Volatile Organic Compounds: Two VOCs (3-octanone and ethanol) were retained in the BERA because an ESL was not available and so HQs could not be calculated. These VOCs were detected in 3 out of 3 and 2 out of 2 surface soil samples, respectively, at very low concentrations (i.e., < 1 mg/kg). Due to the physical and chemical properties of these VOCs (e.g., high vapor pressure; and low bioaccumulative potential), and the relatively low detected concentrations, adverse effects to wildlife due to potential VOC exposure are considered unlikely.

Semi-Volatile Organic Compounds: Two SVOCs (2,6-dinitrotoluene and pentachlorophenol) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. These results are discussed below:

2,6-Dinitrotoluene – 2,6-Dinitrotoluene was detected in 1 out of 24 surface soil samples. The one sample where a detection was noted had a concentration of 0.32 mg/kg. While this concentration was above the ESL of 0.0328 mg/kg, adverse effects to wildlife exposed to 2,6-dinitrotoluene are unlikely given the low frequency of detection and the limited spatial extent of this SVOC. It should be noted that the one detection of 2,6-dinitrotoluene was detected in a sample analyzed for explosives and that a corresponding semi-volatile analysis conducted on the sample did not detected the analyte. It should also be noted that, 2,6-dinitrotoluene was not detected in any other samples analyzed for semi-volatiles or explosives.

<u>Pentachlorophenol</u> – Pentachlorophenol was detected in 2 out of 24 surface soil samples, with concentrations ranging from 0.11 mg/kg to 830 mg/kg. Only one of these concentrations was above the ESL of 2.1 mg/kg. Consequently, adverse effects to wildlife exposed to pentachlorophenol are unlikely given the low frequency of detection and the limited spatial extent of this SVOC.

<u>Pesticides</u>: Three pesticides (4,4'-DDE; dieldrin; and endrin aldehyde) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. These results are discussed below:

<u>4,4'-DDE</u> – 4,4'-DDE was detected in 2 out of 10 surface soil samples, with concentrations ranging from 0.01 mg/kg to 0.04 mg/kg. Only one of these concentrations were greater than the ESL of 0.021 mg/kg, and the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). Based on the limited occurrence and the low calculated HQ, adverse effects to wildlife potentially exposed to 4,4'-DDE are considered unlikely.

<u>Dieldrin</u> – Dieldrin was detected in 1 out of 9 surface soil samples, with a concentration of 0.27 mg/kg. While this concentration was above the ESL of 0.0049 mg/kg, adverse effects to wildlife exposed to dieldrin are unlikely to represent a significant concern due to the limited occurrence at the site.

<u>Endrin aldehyde</u> – Endrin aldehyde was detected in 1 out of 8 surface soil samples, with a concentration of 0.04 mg/kg. This concentration was above the ESL of 0.0105 mg/kg, and the calculated HQ is only slightly above the benchmark value of 1 (HQ=4). Consequently, adverse effects to wildlife exposed to endrin aldehyde are unlikely due to limited occurrence of endrin aldehyde.

<u>Polychlorinated Biphenyls</u>: One PCB, Aroclor 1254, was retained in the BERA because an ESL was not available and so an HQ could not be calculated. Aroclor 1254 was detected in 7 out of 26 surface soil samples.

While there are no Aroclor-specific ESLs from Region 5, Region 5 does provide an ESL of 0.000332 mg/kg for PCBs as a group. The maximum and UCL Aroclor 1254 concentrations at the RY are above this ESL; however, site-specific food chain modeling for the short-tailed shrew and American robin (Section 6.5.4), using conservative exposure assumptions, indicates that the potential risk from exposure to Aroclor 1254 at the RY is very low. Based on these considerations, adverse impacts are not expected for populations of ecological receptors exposed to Aroclor 1254 at the RY.

Inorganics: Five inorganics (aluminum; cobalt; lead; selenium; and zinc) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1, or an HQ could not be calculated because an ESL was not available. These results are discussed below:

Aluminum – Aluminum was detected in 25 out of 25 surface soil samples, with concentrations ranging from 338 mg/kg to 43,600 mg/kg. While no ESL was available for aluminum and an HQ could not be calculated, only one of these concentrations was detected above the site background value, and all of the concentrations were within the range of background concentrations detected at the site. Consequently, adverse effects to wildlife exposed to aluminum are unlikely given the similarity of detected concentrations with the site background value and range.

Cobalt – Cobalt was detected in 24 out of 25 surface soil samples, with concentrations ranging from 1.3 mg/kg to 74.9 mg/kg. While 16 concentrations were above the ESL of 13 mg/kg, only one of these concentrations was detected above the site background value, and all of the concentrations were within the range of background concentrations detected at the site. When an EPC was calculated for cobalt, this value was also below the background value established at the site. In addition, the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). Consequently, adverse effects to wildlife exposed to cobalt are unlikely given the similarity of detected concentrations with the site background values and the low calculated HQ.

Lead – Lead was detected in 25 out of 25 surface soil samples, with concentrations ranging from 1.8 mg/kg to 149 mg/kg. While all but two of these concentrations were above the ESL of 11 mg/kg, all of the concentrations were detected within of the range of background samples found at the site. Consequently, adverse effects to wildlife exposed to lead are unlikely given the similarity of detected concentrations with the site background values.

Selenium – Selenium was detected in 3 out of 22 surface soil samples, with concentrations ranging from 0.43 mg/kg to 1 mg/kg. Only one of these concentrations was above the ESL of 0.52 mg/kg. In addition, the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). Consequently, adverse effects to wildlife exposed to selenium are unlikely given the similarity of detected concentrations with the site background values and the low calculated HQ.

Zinc – Zinc was detected in 25 out of 25 surface soil samples, with concentrations ranging from 7.1 mg/kg to 752 mg/kg. While six concentrations were above the ESL of 46 mg/kg, only one concentration was above the background value established at the site. When an EPC was calculated for zinc, this value was also below the background value established at the site. Consequently, adverse effects to wildlife exposed to zinc are unlikely given the similarity of detected concentrations with the site background values.

Of the COPECs, 20 were also identified as bioaccumulative and were evaluated in the terrestrial food chain model.

6.5.3.2 Sediment

Fifty-four COPECs in sediment were carried forward into the BERA. When refined EPCs were compared with the ESLs, 12 constituents (2-butanone; acetone; carbon disulfide; alpha-chlordane; gamma-chlordane; dieldrin; endrin; heptachlor epoxide; acenaphthene; acenaphthylene; indeno[1,2,3-cd]pyrene; and iron), had a refined HQ greater than 1. In addition, ESLs were not available for 10 other constituents (nitroglycerine; pentaerythritol tetranitrate; dalapon; dicamba; dichlorprop; MCPP; barium; beryllium; and vanadium). The BERA results for sediment COPECs at the RY are presented in Table A.6.ERA-5 and are discussed below:

Explosives: Two explosives (nitroglycerine and pentaerythritol tetranitrate) were retained in the BERA because ESLs were not available and so HQs could not be calculated. Both constituents were detected in 2 out of 11 sediment samples, at very low detected concentrations (i.e., < 1 mg/kg). In addition, both detections of pentaerythritol tetranitrate were located in samples taken from an intermittent ditch that are usually dry, and do not provide high quality aquatic habitat. Based on these considerations, adverse effects to aquatic life due to potential explosive exposure are considered unlikely.

Herbicides: Four herbicides (dalapon; dicamba; dichlorprop; and MCPP) were retained in the BERA because ESLs were not available and so HQs could not be calculated. These four herbicides were each detected in 1 out of 11 samples, at very low concentrations (i.e., < 1 mg/kg). Based on the low concentrations and limited occurrence, adverse effects to aquatic life due to potential herbicide exposure are considered unlikely.

Pesticides: Five pesticides (alpha-chlordane; gamma-chlordane; dieldrin; endrin; and heptachlor epoxide) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. All five of these constituents were detected in the same sample. These results are discussed below:

alpha-Chlordane – alpha-Chlordane was detected in 4 out of 11 sediment samples, with concentrations ranging from 0.00087 mg/kg to 0.0101 mg/kg. Two of these concentrations were above the ESL of 0.00324 mg/kg; however, the calculated HQ for the maximum detected concentration was only slightly above the benchmark value of 1 (HQ=3). Consequently, adverse effects to aquatic life exposed to alpha-chlordane are unlikely given the relatively limited occurrence and low calculated HQ. This COPEC was further evaluated in the aquatic food chain model.

gamma-Chlordane – gamma-Chlordane was detected in 4 out of 11 sediment samples, with concentrations ranging from 0.00081 mg/kg to 0.013 mg/kg. Three of these concentrations were above the ESL of 0.00324 mg/kg; however, the calculated HQ for the maximum detected concentration was slightly above the benchmark value of 1 (HQ=4). Consequently, adverse effects to aquatic life exposed to gamma-chlordane are unlikely given the relatively limited occurrence and low calculated HQ. This COPEC was further evaluated in the aquatic food chain model.

Dieldrin – Dieldrin was detected in 4 out of 11 sediment samples, with concentrations ranging from 0.00174 mg/kg to 0.0041 mg/kg. Three of these concentrations were above the ESL of 0.0019 mg/kg; however, the calculated HQ for the maximum detected concentration was only slightly above the benchmark value of 1 (HQ=2). Consequently, adverse effects to aquatic life exposed to dieldrin are unlikely given the relatively limited occurrence and low calculated HQ. This COPEC was further evaluated in the aquatic food chain model.

Endrin – Endrin was detected in 1 out of 11 sediment samples, with concentration of 0.0125 mg/kg. While this concentration was above the ESL of 0.00222 mg/kg, adverse effects to aquatic life exposed to endrin are unlikely given the low frequency of detection and relatively low concentration. This COPEC was further evaluated in the aquatic food chain model.

Heptachlor epoxide – Heptachlor epoxide was detected in 2 out of 11 sediment samples, with concentrations ranging from 0.00399 mg/kg to 0.00726 mg/kg. Both concentrations were above the ESL of 0.00247 mg/kg; however, the calculated HQ for the maximum detected concentration was only slightly above the benchmark value of 1 (HQ=3). Consequently, adverse effects to aquatic life exposed to heptachlor epoxide are unlikely given the low frequency of detection and relatively low concentration. This COPEC was further evaluated in the aquatic food chain model.

Polycyclic Aromatic Hydrocarbons: Three PAHs (acenaphthene; acenaphthylene; and indeno[1,2,3-cd]pyrene) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. Calculated HQs for these PAHs ranged from 4 to 9. As described in Section 2.4.2.4.1.4, since PAHs were COPECs in this ERA, the ESBTU approach was used to calculate a total TU which was compared to the benchmark of one. TOC ranged between 2.2% to 5.4% in samples collected from across the NRU site and averaged at 3.4%. As previously discussed, a default UF of 2.75 was applied to the total TU to obtain an accurate estimation with 50% confidence. The total TU for all 12 sediment samples taken at the RY were below the benchmark of one (Table A.6.ERA-6), indicating that the potential for adverse effects to aquatic life at the RY is unlikely. In addition, severalPAHs were further evaluated in the aquatic food chain model.

Inorganics: Five inorganics (barium; beryllium; iron; thallium; and vanadium) were retained in the BERA because the calculated HQ was above the benchmark of 1 or because an ESL was not available and so an HQ could not be calculated. These results are discussed below:

Barium – Barium was detected in 14 out of 14 sediment samples, with concentrations ranging from 30.4 mg/kg to 113 mg/kg. While no screening value was available for barium and no background sediment data was collected, all of these detected concentrations were below the soil background value established at the site. Consequently, adverse effects to aquatic life exposed to barium are unlikely given the similarity of detected concentrations with the site background value.

Beryllium – Beryllium was detected in 14 out of 14 sediment samples, with concentrations ranging from 0.42 mg/kg to 1.67 mg/kg. While no screening value was available for beryllium and no background sediment data was collected, all of these detected concentrations were within the range of detected soil background values at the site. Consequently, adverse effects to aquatic life exposed to beryllium are unlikely given the similarity of detected concentrations with the range of site background values.

Iron – Iron was detected in 14 out of 14 sediment samples, with concentrations ranging from 8,760 mg/kg to 79,600 mg/kg. While nine of these concentrations were above the ESL of 20,000 mg/kg, and no background sediment data was collected, all but one of these detected concentrations were below the soil background value established at the site. In addition, when an EPC for iron was calculated, this concentration was below the soil background value at the site. Consequently, adverse effects to aquatic life exposed to iron are unlikely given the similarity of detected concentrations with the soil background value.

Thallium – Thallium was detected in 11 out of 11 sediment samples, with concentrations ranging from 0.07 mg/kg to 0.45 mg/kg. While no screening value was available for thallium and no background sediment data was collected, all of these detected concentrations were within the range of detected soil background values at the site. Consequently, adverse effects to aquatic life exposed to thallium are unlikely given the similarity of detected concentrations with the range of site background values.

Vanadium –Vanadium was detected in 14 out of 14 sediment samples, with concentrations ranging from 16.6 mg/kg to 110 mg/kg. While no screening value was available for vanadium and no background sediment data was collected, all of these detected concentrations were within the range of detected soil background values at the site. Consequently, adverse effects to aquatic life exposed to vanadium are unlikely given the similarity of detected concentrations with the range of site background values.

Of the sediment COPECs carried into the BERA, 28 were identified as bioaccumulative and were evaluated in the aquatic food chain model.

6.5.3.3 Surface Water

Seventeen COPECs in surface water were carried forward into the BERA. When refined EPCs were compared with the ESLs, eight constituents (4,4'-DDT; aluminum; barium; copper; iron; lead; silver; and zinc) had a refined HQ greater than 1. In addition, ESLs were not available for three other constituents (2,4-DB; MCPA; and MCPP). The BERA results for surface water COPECs at the RY are presented in Table A.6.ERA-7 and are discussed below:

Herbicides: Three herbicides (2,4-DB; MCPA; and MCPP) were retained in the BERA because an ESL was not available and so HQs could not be calculated. All three herbicides were detected in only 1 of 6 surface water samples, at very low concentrations (i.e., < 1 mg/L). While no ESLs were available for these constituents, due to the low frequency of detection and the low detected concentrations, adverse effects to aquatic life exposed to herbicides are unlikely.

Pesticides: One pesticide, 4,4'-DDT, was retained in the BERA because the calculated HQ was greater than the benchmark value of 1. This constituent was detected in only 1 out of 6 surface water samples, with a concentration of 0.0027 mg/L. While the calculated HQ of 20 for 4,4'-DDT was above the benchmark of 1, due to the low frequency of detection, it is unlikely that adverse effects to aquatic life exposed to pesticides would occur. 4,4'-DDT was further evaluated in the food chain.

Inorganics: Seven inorganics (aluminum; barium; copper; iron; lead; silver; and zinc) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. These results are discussed below:

Aluminum – Aluminum was detected in 6 out of 7 surface water samples, with concentrations ranging from 0.11 mg/ L to 0.608 mg/L. While all six concentrations were greater than the ESL of 0.087 mg/L, the ESL used from USEPA (2008c) Region 3 and was based on a water quality criterion protective of salmonids (i.e., coldwater habitat species of fish such as trout and salmon), which is likely overly conservative for the type of warmwater habitat (and associated aquatic species) that is prevalent in this locale. When an alternative screening value of 0.46 mg/L from Sample et al. 1996 was used, an HQ of less than 1 was calculated. This alternative screening value is based on the lowest chronic value of aquatic life, and is considered to be a more representative screening value for aluminum at the RY. Based on these considerations, adverse effects to aquatic life exposed to aluminum are unlikely.

Barium – Barium was detected in 6 out of 6 surface water samples, with concentrations ranging from 0.015 mg/L to 0.0796 mg/L. While all six concentrations were greater than the ESL of 0.004 mg/L, the ESL used from USEPA (2008c) Region 3 was based on a secondary chronic value from Suter et al. 1996, and was established using an extremely limited dataset. An alternative aquatic screening value of 0.22 mg/L from USEPA (2008c) Region 5 was found, which is considered to be a more representative screening value. When this ESL was used, an HQ of less than 1 was calculated. This alternative screening value is based on the chronic standards for aquatic life, and is a more representative screening value for barium at the RY. Based on these considerations, adverse effects to aquatic life exposed to barium are unlikely.

Copper – Copper was detected in 1 out of 7 surface water samples, with a concentration of 0.038 mg/L. This concentration was greater than the ESL of 0.009 mg/L, but the calculated HQ was only slightly greater than the benchmark value of 1 (HQ=4). In addition, the ESL is based on a default hardness value of 100 mg/L. A site-specific hardness value of 195 mg/L (average at the RY area) was used to calculate an ESL of 0.01585 mg/L. When this ESL was used, an HQ of 2 was calculated, which again is only slightly above the benchmark value of 1. Based on the low HQ calculations and the limited occurrence in surface water, adverse effects to aquatic life exposed to copper are unlikely. Copper was further evaluated in the aquatic food chain model.

Iron – Iron was detected in 6 out of 7 surface water samples, with concentrations ranging from 0.127 mg/L to 4.47 mg/L. While three of these concentrations were greater than the ESL of 0.3 mg/L, as previously stated, the surface water samples were not filtered, and as such the results represent total iron. Therefore, it is not known what portion, if any, of the iron is in the dissolved (i.e., filtered) form. It is possible that even though the total iron concentrations exceed the ESL, the dissolved (and therefore bioavailable) iron concentrations may in actuality not exceed the ESL. Consequently, adverse effects to aquatic life exposed to iron are unlikely.

Lead – Lead was detected in 5 out of 7 surface water samples, with concentrations ranging from 0.00088 mg/L to 0.031 mg/L. Only one of these concentrations was greater than the ESL of 0.0025 mg/L, and the calculated HQ was only slightly above the benchmark value of 1 (HQ=3). This HQ was based on an ESL value derived using a default hardness value of 100 mg/L. A site-specific hardness value of 195 mg/L (average at the RY area) was used to calculate an ESL of 0.03161 mg/L. When this ESL was used, an HQ of less than 1 was calculated. Consequently, adverse effects to aquatic life exposed to lead are unlikely. This COPEC was further evaluated in the aquatic food chain model.

<u>Silver</u> – Silver was detected in 2 out of 6 surface water samples, with concentrations ranging from 0.0052 mg/L to 0.0083 mg/L. While both concentrations were above the ESL of 0.0032 mg/L, the calculated HQ was only slightly above the benchmark value of 1 (HQ=3). This HQ was based on an ESL value derived using a default hardness value of 100 mg/L. A site-specific hardness value of 195 mg/L (average at the RY area) was used to calculate an ESL of 0.01088 mg/L. When this ESL was used, an HQ of less than 1 was calculated. Consequently, adverse effects to aquatic life exposed to silver are unlikely.

<u>Zinc</u> – Zinc was detected in 2 out of 7 surface water samples, with concentrations ranging from 0.0076 mg/L to 0.274 mg/L. Only one of these concentrations was above the ESL of 0.12 mg/L, and the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). This HQ was based on an ESL value derived using a default hardness value of 100 mg/L. A site-specific hardness value of 195 mg/L (average at the RY area) was used to calculate an ESL of 0.208 mg/L. When this ESL was used, an HQ of 1 was calculated. Consequently, adverse effects to aquatic life exposed to zinc are unlikely. In addition, zinc was further evaluated in the aquatic food chain model.

Of the COPECs 10 were also identified as bioaccumulative and were evaluated in the aquatic food chain model.

6.5.4 Refinement of Assessment and Measurement Endpoints for Bioaccumulative COPECs

Food chain modeling was conducted at the RY in order to evaluate the potential ecological effects of the bioaccumulative COPECs in soil, sediment, and surface water on the receptors identified in Section 2.4. COPECs identified in soil were evaluated in the terrestrial food chain, and COPECs identified in sediment and surface water were evaluated in the aquatic food chain. The results for both the maximum and refined scenarios of these models are presented in Tables A.6.ERA-8 through A.6.ERA-15, and the results of each of the refined scenarios are discussed in the subsections below.

6.5.4.1 Terrestrial Food chain Model

The refined scenario NOAEL and LOAEL HQs for both the short-tailed shrew (Tables A.6.ERA-8 and A.6.ERA-9) and the American robin (Tables A.6.ERA-10 and A.6.ERA-11) were less than or equal to 1 for most of the bioaccumulative COPECs identified at the RY. Two other constituents, pentachlorophenol and zinc, had HQs greater than 1 for the short-tailed shrew as discussed below.

Pentachlorophenol had HQs of 100 (NOAEL) and 10 (LOAEL). The NOAEL is a very conservative screening criterion, while the LOAEL indicates a concentration above which adverse impacts to individual mammals may occur. Based on this information and considering the low frequency of detection of this constituent (i.e., 8 % in surface soil), these results indicate that individual shrews (or other insectivorous mammals) exposed to pentachlorophenol are not expected to experience adverse effect.

Zinc also had a NOAEL above the benchmark of one for the short-tailed shrew. This inorganic had a refined shrew NOAEL of 2, which is only slightly above 1, and a LOAEL of 0.2, which is below the benchmark of 1. As previously discussed, the NOAEL is a very conservative screening criterion, while the LOAEL indicates a concentration above which adverse impacts to individual mammals may occur. Given that the EPC of 186.4 mg/kg was below the background concentration of 202 mg/kg established at the site and based on the low detected concentrations, these results indicate that individual shrews (or other insectivorous mammals) potentially exposed to zinc are not expected to experience adverse effects.

Based on the overall analysis of terrestrial food chain modeling HQs and consideration of the limited spatial extent of impacted soils, adverse effects are not expected for short-tailed shrews (and other insectivorous mammals) and American robins (and other insectivorous birds) populations exposed to bioaccumulative COPECs in soil at the RY.

6.5.4.2 Aquatic Food chain Model

As summarized in Table A.6.ERA-17, the refined scenario NOAEL and LOAEL HQs for both the mink (Tables A.6.ERA-12 and A.6.ERA-13) and the great blue heron (Tables A.6.ERA-14 and A.6.ERA-15) were less than or equal to 1 for all of the bioaccumulative COPECs identified in sediment and/or surface water, with the exception of the mink NOAEL (HQ=2) and LOAEL (HQ=0.2) for zinc.

As previously discussed, the NOAEL, is a very conservative screening criterion, while the LOAEL indicates a concentration above which adverse impacts to individual mammals may occur. Based on this information and considering the low frequency of detection of this constituent, these results indicate that individual mink and herons (or other piscivorous mammals and birds) exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of aquatic food chain modeling HQs, adverse effects are not expected for mink (and other piscivorous mammals) and great blue herons (and other piscivorous birds) populations potentially exposed to bioaccumulative COPECs in sediment and/or surface water at the RY.

6.5.5 Ecological Risk Summary

Screening-level and baseline risk assessments were completed for the RY. After the SLERA, 42 constituents were selected as COPECs in surface soil, 54 constituents were selected as COPECs in sediment, and 17 constituents were selected as COPECs in surface water because the HQs were greater than 1, considered bioaccumulative or an HQ could not be calculated because an ESL was not available. After the BERA, 36 constituents in surface soil, 50 constituents in sediment, and 16 constituents in surface water were retained because the HQs were greater than 1 or an HQ could not be calculated because an ESL was not available. Food chain modeling was evaluated for all those constituents identified as bioaccumulative.

Tables A.6.ERA-16 and A.6.ERA-17 summarize the constituents in surface soil, sediment, and surface water carried through the BERA and evaluated in the terrestrial and/or aquatic food chain models. As shown in these tables, all constituents evaluated in the terrestrial and aquatic food chain refined scenarios had LOAEL and NOAEL HQs less than or equal to 1, with the exception of shrew HQs for pentachlorophenol and zinc and mink HQs for zinc. However, these HQs are based on the very conservative screening criterion of the NOAEL. In addition, there was a low frequency of detection of pentachlorophenol in surface soil and the EPC for zinc is very similar to its established site background concentration. Furthermore, zinc was not identified as a direct contact COPEC for sediment indicating that direct contact of ecological receptors with the zinc in sediment was not likely to result in any adverse effects. These results indicate that individual shrews (or other insectivorous mammals) and individual minks (or other piscivorous mammals) potentially exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of the ERA for the RY, the results indicate that adverse effects are not expected for wildlife at the site.

6.6 RY Summary and Conclusions

The HHRA for the RY evaluated current and future land-use conditions for site workers and hypothetical future use for construction workers and adult and child residents. Exposure of these receptors to the soil, sediment, and surface water COPCs was evaluated in the risk assessment. Although exposure to VOCs in soil migrating into buildings was identified as a potential exposure pathway, inhalation toxicity values were not available for the two VOCs, 3-octanone and ethanol, identified as soil COPCs at the RY. Therefore, this exposure pathway was not evaluated quantitatively.

A current or future site worker could be present at the RY area, and could be exposed to surface soil, sediment, or surface water. The total cumulative ELCR for site workers exposed to surface soil, sediment, and surface water at the RY is 1×10^{-4}, which is equal to the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.4, which is less than the benchmark of 1.

A hypothetical future construction worker could be present at the RY area, and could be exposed to combined surface and subsurface soil. The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the RY is 5×10^{-6}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 0.7, which is less than the benchmark of 1.

A hypothetical future resident could be present at the RY area, and could be exposed to combined surface and subsurface soil, sediment, or surface water. The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water at the RY is 3×10^{-4}, which is slightly above the high end of the USEPA target risk range of 10^{-6} to 10^{-4}. This risk driver for cancer risk is pentachlorophenol, which was detected in two samples, one at an estimated value of 0.11 mg/kg and one at a maximum concentration of 830 mg/kg. The one high detection was from a sample collected in April of 1998 and the results were not duplicated in subsequent sampling. The risk assessment was based on the maximum detected concentration and thus likely overestimates potential exposures.

Rail Yard

The total cumulative HI for hypothetical future adult residents is 0.6, which is less than the benchmark of 1.

The total cumulative HI for hypothetical future child residents is 3, which is greater than the benchmark of 1. The primary contributor to the non-cancer hazard above 1 is cobalt. The maximum cobalt concentration of 74.9 mg/kg is only slightly greater than the background concentration of 72.3 mg/kg and is well within the range of background levels. Therefore, it is likely that cobalt is present due to naturally occurring sources rather than due to activities at the RY.

The results of the human health risk assessment indicate that use of the RY for industrial uses should not result in unacceptable risks to potential receptors.

A SLERA and BERA were completed for the RY, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that a few of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to individual insectivorous mammals and birds exposed to surface soils and individual piscivorous mammals and birds exposed to sediment and/or surface water, if all exposure assumptions are met. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, adverse impacts at the population-level are considered unlikely for the shrew (or other insectivorous mammals) and the robin (or other insectivorous birds) exposed to the constituents at the RY.

7. Western Burning Ground (WBG)

7.1 Site Description and History

The WBG is a former burning ground located in the southwestern portion of the RFAAP-NRU, south of the IAA. The WBG was used as a burning ground to decontaminate explosives contaminated material and to dispose of excess and off-spec explosives/energetics. The main burn area was approximately 170 ft long by 100 ft wide and is surrounded on three sides by an approximately 4 ft high earthen berm. A dirt road runs parallel to the open side of the former burn area, leading north to Alger Road, and south to the top of a steep slope above an unnamed pond. The dirt road was reportedly constructed on top of an ashy layer of material extending from the burning ground at the time of the pond construction. The pond was constructed during the early 1990s and is fed by Wiggins Spring at the northwest (upgradient) end of the pond. The pond also collects runoff from the surrounding area through a series of storm water ditches/culverts. The WBG is no longer active.

7.2 Physical Setting

The WBG area is generally flat at an elevation of approximately 2,050 ft amsl but slopes increase to the south and southwest towards Wiggins Spring and an unnamed pond. Surface water runoff from the former burn area is expected to flow to the southwest. A small, unlined drainage ditch captures some runoff, channeling flow to the northwest before intersecting a second ditch that drains into the pond. The site is surrounded with wooded areas.

The unnamed pond, which is approximately 3.6 acres in size, was constructed south of the WBG during the early 1990s. The pond is fed by Wiggins Spring, a natural spring located at the head (i.e., northwest corner) of the pond. The pond also collects surface water drainage from the surrounding area. The pond drains under an earthen dam via a constant level drain on the southeastern side of the pond. The effluent flows into a tributary of the unnamed creek (UNC-NRU) that flows through the southwest portion of the RFAAP-NRU.

7.3 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. Risk assessment datasets for soil, sediment, surface water, and fish tissue for the WBG were prepared then summarized and statistically analyzed per methods described in Section 2.1. Risk assessment dataset summaries were prepared highlighting the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPCs. To prepare a dataset representing what site conditions might be should the pond at the WBG be drained, data from soils and sediment were combined to calculate an EPC representing the merged samples. This information is presented in Tables A.7.Data-1 through A.7.Data-5.

Data for fish fillets and whole body fish (Tables A.7.Data-6 and A.7.Data-8, respectively) were each presented for use in the risk assessment datasets. The fish filets data were used in the HHRA and the whole body data were used in the ERA.

7.4 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with constituents detected in soil, sediment, surface water, and fish tissue samples collected at the WBG. The risk assessment approach follows the Radford Army Ammunition Plant Final Master Work Plan (URS 2003).

The risk assessment approach is based on Virginia and USEPA guidance for risk assessments (VDEQ 2008; USEPA 2004a; 2000a; 1997a; 1992; 1991a; 1989). This section summarizes the occurrence of constituents in each medium and identifies COPCs at the WBG for the human health risk assessment; identifies the potential human exposure scenarios relevant to the WBG; and presents the estimated human health risks associated with the identified COPCs and the relevant human exposure scenarios at the WBG. Methodologies for data summary and selection of COPCs, exposure assessment, and toxicity assessment for the HHRA were presented in Section 2.3.

7.4.1 Selection of Constituents of Potential Concern

This section discusses the selection of COPCs for each medium.

7.4.1.1 Surface Soil

Surface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.7.HHRA-1 presents the selection of surface soil COPCs for the HHRA. As summarized in Table A.7.HHRA-1, 14 constituents were identified as COPCs in surface soil as follows:

Six VOCs (acetone; carbon disulfide; d-limonene; methylene chloride; p-isopropyltoluene; and toluene) were detected in surface soil. All of these constituents were detected below the USEPA (2009a) residential soil RSL values with the exception of d-limonene, which did not have a USEPA (2009a) residential soil RSL value. As a result, only d-limonene was identified as a COPC for surface soil.

Seven SVOCs (bis[2-ethylhexyl]phthalate; butylbenzylphthalate; carbazole; dibenzofuran; di-n-butylphthalate; di-n-octylphthalate; and n-nitrosodiphenylamine) were detected in surface soil. All of these constituents were detected below the USEPA (2009a) residential soil RSL values with the exception of carbazole, which did not have a value. As a result, carbazole was identified as a COPC for surface soil.

Seventeen dioxin/furan compounds (1,2,3,4,6,7,8-HpCDD; 1,2,3,4,6,7,8-HpCDF; 1,2,3,4,7,8,9-HpCDF; 1,2,3,4,7,8-HxCDD; 1,2,3,4,7,8-HxCDF; 1,2,3,6,7,8-HxCDD; 1,2,3,6,7,8-HxCDF; 1,2,3,7,8,9-HxCDD; 1,2,3,7,8,9-HxCDF; 1,2,3,7,8-PeCDD; 1,2,3,7,8-PeCDF; 2,3,4,6,7,8-HxCDF; 2,3,4,7,8-PeCDF; 2,3,7,8-TCDD; 2,3,7,8-TCDF; OCDD; and OCDF) were detected in surface soil. All of these constituents were detected below the USEPA (2009a) residential soil RSL values, and as a result, were not identified as COPCs for surface soil.

One explosive, pentaerythritol tetranitrate, was detected in surface soil. This constituent did not have a USEPA (2009a) residential soil RSL value; as a result, pentaerythritol tetranitrate was identified as a COPC for surface soil.

Four herbicides (2,4,5-TP; 2,4-D; dalapon; and MCPP) were detected in surface soil. All of these constituents were detected below the USEPA (2009a) residential soil RSL values, and as a result, were not identified as COPCs for surface soil.

Two pesticides (4,4'-DDD and dieldrin) were detected in surface soil. Both of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values, and as a result, were not identified as COPCs for surface soil.

Seventeen PAHs (2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in surface soil. Five of these detected constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene) were detected at concentrations greater than their respective USEPA (2009a) residential soil RSL values and were identified as COPCs for surface soil.

One PCB, Aroclor 1254, was detected in surface soil. This constituent was detected below the USEPA (2009a) residential soil RSL value and was not identified as a COPC for surface soil.

Twenty-three inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; silver; sodium; thallium; vanadium; and zinc) were detected in surface soil. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Eleven of these constituents (aluminum; antimony; arsenic; cobalt; copper; iron; lead; manganese; thallium; vanadium; and zinc) were detected at concentrations greater than the USEPA (2009a) residential soil RSL values. However, aluminum, cobalt, manganese, thallium, and vanadium were all detected below the background concentrations. As a result, only antimony, arsenic, copper, iron, lead, and zinc were identified as COPCs for surface soil.

7.4.1.2 Combined Surface and Subsurface Soil

Combined surface and subsurface soil COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.7.HHRA-2 presents the selection of combined surface and subsurface soil COPCs for the HHRA. As summarized in Table A.7.HHRA-2, 17 constituents were identified as COPCs in combined surface and subsurface soil as follows:

Six VOCs (acetone; carbon disulfide; d-limonene; methylene chloride; p-isopropyltoluene; and toluene) were detected in combined surface and subsurface soil. All of these constituents were detected below the USEPA (2009a) residential soil RSL values with the exception of d-limonene, which did not have a USEPA (2009a) residential soil RSL value. As a result, only d-limonene was identified as a COPC for combined surface and subsurface soil.

Seven SVOCs (bis[2-ethylhexyl]phthalate; butylbenzylphthalate; carbazole; dibenzofuran; di-n-butylphthalate; di-n-octylphthalate; and n-nitrosodiphenylamine) were detected in combined surface and subsurface soil. All of these constituents were detected below the USEPA (2009a) residential soil RSL values with the exception of carbazole, which did not have a value. As a result, carbazole was identified as a COPC for combined surface and subsurface soil.

Seventeen dioxin/furan compounds (1,2,3,4,6,7,8-HpCDD; 1,2,3,4,6,7,8-HpCDF; 1,2,3,4,7,8,9-HpCDF; 1,2,3,4,7,8-HxCDD; 1,2,3,4,7,8-HxCDF; 1,2,3,6,7,8-HxCDD;

1,2,3,6,7,8-HxCDF; 1,2,3,7,8,9-HxCDD; 1,2,3,7,8,9-HxCDF; 1,2,3,7,8-PeCDD; 1,2,3,7,8-PeCDF; 2,3,4,6,7,8-HxCDF; 2,3,4,7,8-PeCDF; 2,3,7,8-TCDD; 2,3,7,8-TCDF; OCDD; and OCDF) were detected in combined surface and subsurface soil. Only one constituent, 1,2,3,7,8-PeCDD, was detected at a maximum concentration greater than the USEPA (2009a) residential soil RSL values and was identified as a COPC for combined surface and subsurface soil.

One explosive, pentaerythritol tetranitrate, was detected in combined surface and subsurface soil. This constituent did not have a USEPA (2009a) residential soil RSL value; as a result, pentaerythritol tetranitrate was identified as a COPC for combined surface and subsurface soil.

Four herbicides (2,4,5-TP; 2,4-D; dalapon; and MCPP) were detected in combined surface and subsurface soil. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values, and as a result, were not identified as COPCs for combined surface and subsurface soil.

Two pesticides (4,4'-DDD and dieldrin) were detected in combined surface and subsurface soil. Both of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values, and as a result, were not identified as COPCs for combined surface and subsurface soil.

Seventeen PAHs (2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in combined surface and subsurface soil. Five of these detected constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene) were present at concentrations greater than the USEPA (2009a) residential soil RSL values and were identified as COPCs for combined surface and subsurface soil.

One PCB, Aroclor 1254, was detected in combined surface and subsurface soil. This constituent was detected at concentrations above the USEPA (2009a) residential soil RSL value and was identified as a COPC for combined surface and subsurface soil.

Twenty-three inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; silver; sodium; thallium; vanadium; and zinc) were detected in combined surface and subsurface soil. Four constituents (calcium;

magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Eleven of these constituents (aluminum; antimony; arsenic; cobalt; copper; iron; lead; manganese; thallium; vanadium; and zinc) were greater than the USEPA (2009a) residential soil RSL values. However, cobalt, manganese, thallium, and vanadium were all detected below the background concentrations. As a result, only aluminum, antimony, arsenic, copper, iron, lead, and zinc were identified as COPCs for combined surface and subsurface soil.

7.4.1.3 Sediment

Sediment COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for residential soil. Table A.7.HHRA-3 presents the selection of sediment COPCs for the HHRA. As summarized in Table A.7.HHRA-3, 17 constituents were identified as COPCs in sediment as follows:

Five VOCs (2-butanone; acetone; carbon disulfide; methylene chloride; and toluene) were detected in sediment. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values and were not identified as COPCs in sediment.

Seven SVOCs (1,2,4-trichlorobenzene; 1,4-dichlorobenzene; 4-methylphenol; bis[2-ethylhexyl]phthalate; carbazole; dibenzofuran; and phenol) were detected in sediment. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values with the exception of carbazole, which did not have a value. As a result, only carbazole was identified as a COPC for sediment.

Thirteen dioxin/furan compounds (1,2,3,4,6,7,8-HpCDD; 1,2,3,4,6,7,8-HpCDF; 1,2,3,4,7,8,9-HpCDF; 1,2,3,4,7,8-HxCDD; 1,2,3,4,7,8-HxCDF; 1,2,3,6,7,8-HxCDD; 1,2,3,6,7,8-HxCDF; 1,2,3,7,8,9-HxCDD; 2,3,4,6,7,8-HxCDF; 2,3,4,7,8-PeCDF; 2,3,7,8-TCDF; OCDD; and OCDF) were detected in sediment. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values, and as a result, were not identified as COPCs for sediment.

Two explosives (1,3,5-trinitrobenzene and nitroglycerine) were detected in sediment. Only nitroglycerine was detected at concentrations above the USEPA (2009a) residential soil RSL value and was identified as a COPC in sediment.

Four herbicides (2,4,5-T; 2,4-D; dicamba; and MCPP) were detected in sediment. All of these constituents were detected at concentrations below the USEPA (2009a) residential soil RSL values and were not identified as COPCs in sediment.

Eleven pesticides (4,4'-DDD; 4,4'-DDE; 4,4'-DDT; delta-BHC; alpha-chlordane; gamma-chlordane; dieldrin; endosulfan II; endrin aldehyde; endrin ketone; and methoxyclor) were detected in sediment; however, all of these constituents were detected at concentrations below their respective USEPA (2009a) residential soil RSL values and were not identified as COPCs in sediment.

Eighteen PAHs (1-methylnaphthalene; 2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in sediment. Five of these detected constituents (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene) were present at concentrations greater than the USEPA (2009a) residential soil RSL values and were identified as COPCs in sediment.

Twenty-three inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; silver; sodium; thallium; vanadium; and zinc) were detected in sediment. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Ten of these constituents (aluminum; arsenic; chromium; cobalt; iron; lead; manganese; thallium; vanadium; and zinc) were greater than the USEPA (2009a) residential soil RSL values. Consequently, only aluminum, arsenic, chromium, cobalt, iron, lead, manganese, thallium, vanadium, and zinc were identified as COPCs for sediment.

7.4.1.4 Surface Water

Surface water COPCs were selected by comparing the analytical data with USEPA (2009a) RSLs for tap water. Table A.7.HHRA-4 presents the selection of surface water COPCs for the HHRA. As summarized in Table A.7.HHRA-4, 10 constituents were identified as COPCs in surface water as follows:

Eight VOCs (2-butanone; acetone; carbon disulfide; chloroform; cis-1,2-dichloroethene; tetrachloroethene; toluene; and trichloroethene) were detected in surface water. Two of these detected constituents, chloroform and tetrachloroethene, were detected at concentrations greater than their USEPA (2009a) tap water RSL values and were identified as COPCs for surface water.

Eight SVOCs (1,2-dichlorobenzene; 1,4-dichlorobenzene; 1,4-dichlorobenzene; benzoic acid; bis[2-ethylhexyl]phthalate; butylbenzylphthalate; diethylphthalate; and di-n-butylphthalate) were detected at concentrations in surface water. All of these constituents were detected below the USEPA (2009a) tap water RSL values and were not identified as COPCs for surface water.

One dioxin/furan compound, OCDD, was detected in surface water. This constituent was detected at concentrations below the USEPA (2009a) tap water RSL value and was not identified as a COPC for surface water.

One explosive, m-nitrotoluene, was detected in surface water. This constituent was detected at concentrations below the USEPA (2009a) tap water RSL value and was not identified as a COPC for surface water.

Two herbicides (2,4-D and MCPP) were detected in surface water. Only MCPP was detected at concentrations above the USEPA (2009a) tap water RSL value, and as a result, was identified as a COPC for surface water.

One pesticide, dieldrin, was detected in surface water. This constituent was at a maximum concentration greater than the USEPA (2009a) tap water RSL value and was identified as a COPC for surface water.

Seven PAHs (1-methylnaphthalene; 2-methylnaphthalene; acenaphthene; anthracene; fluorene; naphthalene; and phenanthrene) were detected in surface water. All of these constituents were detected at concentrations below their respective USEPA (2009a) tap water RSL values and were not identified as COPCs for surface water.

Eighteen inorganics (aluminum; arsenic; barium; beryllium; calcium; copper; iron; lead; magnesium; manganese; nickel; potassium; selenium; silver; sodium; thallium; vanadium; and zinc) were detected in surface water. Four constituents (calcium; magnesium; potassium; and sodium) were identified as essential nutrients and were not evaluated further in the HHRA. Five of these detected constituents (arsenic; iron; lead; manganese; thallium; and vanadium) were detected above the USEPA (2009a) tap water RSL values. As a result, only arsenic, iron, lead, manganese, thallium, and vanadium were identified as COPCs for surface water.

7.4.1.5 Fish Tissue

Fish tissue COPCs were to be selected by comparison to acceptable consumption levels (USEPA 2000); however, none of the constituents detected had identified acceptable consumption levels. As a result, all constituents detected with the exception of essential nutrients were selected as fish tissue COPCs. Table A.7.HHRA-5 presents the selection fish tissue COPCs for the HHRA.

The analyte list as presented in Table A.7.HHRA-5 was based upon constituent detections of fish samples. A total of 16 fish tissue samples were collected from the WBG pond and analyzed for TCL PCBs and TAL metals. Analysis of the fish tissue indicated detections of 11 metals with the remaining analytes being non-detects (see Table 9-16 of main document). The 11 fish tissue detections presented in Table 9-16 where then used for the selection fish tissue COPCs.

As a conservative measure, maximum concentrations were used as EPCs for fish ingestion. As summarized in Table A.7.HHRA-5, the following constituents were identified as COPCs in fish tissue for the HHRA: barium, chromium, copper, iron, manganese, mercury, and zinc.

7.4.2 Summary of Selected Constituents of Potential Concern

Fourteen constituents were selected as COPCs in surface soil at the WBG, including one VOC (d-limonene), one SVOC (carbazole), five PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene), one explosive (pentaerythritol tetranitrate), and six inorganics (antimony; arsenic; copper; iron; lead; and zinc).

Seventeen constituents were selected as COPCs in combined surface and subsurface soil at the WBG, including one VOC (d-limonene), one SVOC (carbazole), five PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene), one dioxin compound (1,2,3,7,8-PeCDD), one PCB (Aroclor 1254), one explosive (pentaerythritol tetranitrate), and seven inorganics (aluminum; antimony; arsenic; copper; iron; lead; and zinc).

Seventeen constituents were selected as COPCs in sediment at the WBG, including one SVOC (carbazole), five PAHs (benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; dibenzo[a,h]anthracene; and indeno[1,2,3-cd]pyrene), one explosive (nitroglycerine), and ten inorganics (aluminum; arsenic; chromium; cobalt; iron; lead; manganese; thallium; vanadium; and zinc).

Ten constituents were selected as COPCs in surface water at the WBG, including two VOCs (chloroform and tetrachloroethene), one herbicide (MCPP), one pesticide (dieldrin), and six inorganics (arsenic; iron; lead; manganese; thallium; and vanadium).

Seven COPCs were selected as COPCs in fish tissue at the WBG and they are: barium, chromium, copper, iron, manganese, mercury, and zinc.

7.4.3 Determination of Exposure Point Concentrations

Fourteen constituents were selected as COPCs in surface soil, seventeen constituents were selected as COPCs in and combined surface and subsurface soil, seventeen constituents were selected as COPCs in sediment, and ten constituents were selected as COPCs in surface water because the maximum detected concentrations were greater than the corresponding USEPA (2009a) RSL or no RSL was available. The distribution testing and UCL calculations were performed as described in Section 2.2.6.1, and the EPCs for these COPCs are summarized in Table A.7.HHRA-6.

7.4.4 Human Health Risk Characterization

Excess lifetime cancer risks and non-cancer hazards were calculated per methods described in section 2.2.4.1 and 2.2.4.2. Blood lead level estimates were calculated using methods described in Section 2.2.4.3. The physical and chemical properties and toxicity values used to evaluate excess lifetime cancer risks and non-cancer hazards are presented in Tables A.2-3 through A.2-9. The exposure assumptions used to evaluate potentially exposed receptors are presented in Table A.2-10. The equations used in the risk characterization calculations are presented in Tables A.2-11 through A.2-15.

The soil, sediment, and surface water COPCs were evaluated for direct contact. VOCs identified as COPCs in the WBG were also evaluated for inhalation via vapor migration into buildings. One VOC, d-limonene, was identified as a soil COPC at the WBG. This COPC does not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area.

The excess lifetime cancer risks and non-cancer hazards and the estimated blood lead levels for each potentially exposed receptor included in the risk assessment for the WBG are discussed by receptor in following subsections. In addition to the site worker, construction worker, and resident scenarios evaluated for all areas, two additional sets of exposures were evaluated for the WBG area: exposures to participants (adults and children) who might be exposed to sediment via wading during the annual two-day fish rodeo; and exposures to site workers, hypothetical construction workers, and hypothetical future residents (adults and children) for whom soil exposure would encompass both current soil and sediment in the event that the pond at the WBG were drained.

7.4.4.1 Site Worker

A current or future site worker could be present at the WBG area, and could be exposed to surface soil, sediment, or surface water. The ELCR and non-cancer hazard index for site worker exposure to each medium are presented in Tables A.7.HHRA- 7 through A.7.HHRA-9, and are summarized in Table A.7.HHRA-25. As presented in the table above, the ELCRs for surface soil, sediment, and surface water are all within the USEPA target risk range, and the HIs for each medium are all below the benchmark value of 1.

The total cumulative ELCR for site workers exposed to surface soil, sediment, and surface water at the WBG is 1×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.4, which is less than the benchmark of 1.

The 50^{th} percentile blood lead level estimates for the site worker receptor, as seen in Table A.7.HHRA-27, from exposure to lead in soil was calculated to be 2 µg/dL and the 95^{th} percentile fetal blood lead levels was at 7 µg/dL. Both of these estimated blood lead levels are below the benchmark of 10 µg/dL.

7.4.4.2 Hypothetical Future Construction Worker

A hypothetical future construction worker could be present at the WBG area, and could be exposed to combined surface and subsurface soil. The ELCR and non-cancer hazard index for hypothetical future construction worker exposure to soil are presented in Table A.7.HHRA-10, and are summarized in Table A.7.HHRA-25.

The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the WBG is 5×10^{-7}, which is below the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 0.5, which is less than the benchmark of 1.

The 50^{th} percentile blood lead level estimates for the hypothetical future construction worker, as seen in Table A.7.HHRA-30, from exposure to lead in soil was calculated to be 2 µg/dL and the 95^{th} percentile fetal blood lead levels was at 7 µg/dL. Both of these estimated blood lead levels are below the benchmark of 10 µg/dL.

7.4.4.3 Hypothetical Future Residents

A hypothetical future resident could be present at the WBG area, and could be exposed to combined surface and subsurface soil, sediment, or surface water. The ELCRs and non-cancer HIs for hypothetical future resident exposure to each medium are presented in Tables A.7.HHRA-11 through A.7.HHRA-18, and are summarized in Table A.7.HHRA-25.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, surface water, and ingestion of fish at the WBG is 5×10^{-5} , which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}.

The total cumulative HI for hypothetical future adult residents is 0.8, which is less than the benchmark of 1.

The total cumulative HI for hypothetical future child residents is 6, which is above the benchmark of 1. When the HI for combined surface and subsurface soil is segregated into target site and critical effects, none of the hazards is above the benchmark of 1. When the HI for sediment is segregated into target site and critical effects, only the HI for chromium (which is based on a toxicological study in which no effects were observed via the oral route) exceeded the benchmark of 1. When the HI for fish ingestion is segregated by target site and critical effects, the HIs are all less than or equal to 1.

Lead was a COPC in both soil and sediments at the WBG. Exposure to the sediments is intermittent, but exposure to sediments needs to be combined with the exposure to soil to calculate a cumulative exposure to lead for each receptor. As a result, a time-weighted average lead concentration was calculated assuming 350 days/year exposure to lead in soil and 48 days/year exposure to lead in sediments. This resulted in an EPC of 623 mg/kg of lead. As shown on Table A.7.HHRA-29, the 50^{th} percentile blood lead level estimates for the adult resident receptor from exposure to lead in soil and sediment was calculated to be 2.8 µg/dL and the 95^{th} percentile fetal blood lead level was 10 µg/dL. The adult level is well below the benchmark and the fetal level is at the benchmark.

The IEUBK model for childhood exposure to lead includes the contribution of exposure to lead in dust. The time-weighted exposure point concentration included both soil and sediment contributions. However, soil is more likely to contribute to dust exposure than would sediment. As a result, the dust concentration was based on the soil EPC and was set at 70 mg/kg for the entire exposure period. As shown on Table A.7.HHRA-28, blood lead level estimates for the hypothetical child resident receptor from exposure to lead in soil and sediment were evaluated and the predicted annual blood lead levels ranged from 2.9 µg/dL to 5.5 µg/dL. Exposure of a child over a seven year period resulted in a geometric mean blood lead concentration of 4.26 µg/dL, below the 10 µg/dL benchmark, and a prediction of 3 percent of the population having blood lead concentrations above the 10 µg/dL benchmark.

7.4.4.4 Fish Rodeo Participants

Potential risks were evaluated for participants in the semi-annual fishing rodeo held at the WBG pond. The fishing rodeo would occur two days per year. Individuals who catch fish would be allowed to retain them. However, as the pond would be stocked with fish just before the rodeo begins, it is not likely that they would accumulate any COPCs during that time. Thus, the only potential risk to adults and children who participate in the rodeo would be through direct contact with sediments. Accordingly, ELCRs and HIs for this potential sediment exposure were calculated by using exposure factors for the residential scenario modified to replace the exposure frequency from 48 days/year to 2 days/year. The ELCRs and non-cancer hazard index for hypothetical adult and child partipants in the fish rodeo are presented in Tables A.7.HHRA-19 and A.7.HHRA-20.

The ELCR for the hypothetical fish rodeo participants exposed to sediments at the WBG was 4×10^{-7} which is below the USEPA target risk range of 1 x 10-6 to 1 x 10-4. The total cumulative HI for adult participants was 0.009, which is substantially less than the benchmark of 1. The total cumulative HI for child participants was 0.08, which is also less than the benchmark.

7.4.4.5 Site Worker, Hypothetical Future Construction Worker, and Hypothetical Resident – Drained Pond

The HHRA for the WBG area also estimated hypothetical risks to current and future site workers, hypothetical future construction workers, and hypothetical future residents if the pond is drained in the future, which could result in current sediments becoming part of the soil to which these residents might be exposed. To complete this evaluation, the EPCs were modified to represent combined soil and sediment samples. Exposure factor values were otherwise identical to those used in the evaluation of exposure to soils for these receptors. If the pond were to be drained, wading and fishing would no longer be possible, so exposures by those pathways were not included when characterizing risks if the pond were drained in the future. The ELCRs and HIs for potential receptors under a future drained pond scenario are presented in Tables A.7.HHRA-21 through A.7.HHRA-24 and summarized in Table A.7.HHRA-26.

The total cumulative ELCR for future site workers exposed to combined combined surface soil, subsurface soil, and current sediment at the WBG was 1×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future site workers is 0.5, which is less than the benchmark of 1.

The total cumulative ELCR for hypothetical future construction workers exposed to combined combined surface soil, subsurface soil, and current sediment at the WBG was 6×10^{-7}, which is below the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 0.8, which is less than the benchmark of 1.

The total cumulative ELCR for hypothetical future residents exposed to combined surface soil, subsurface soil, and current sediment at the WBG was 5×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical adult residents is 0.7, which is below the benchmark of 1. The total cumulative HI for hypothetical child residents is 6, which is greater than the benchmark value of 1. When the HI is segregated into target site and critical effects, only the HI for chromium (which is based on a toxicological study in which no effects were observed via the oral route) exceeded the benchmark of 1.

These results indicate that risks to future site workers, hypothetical future construction workers, or hypothetical future adult residents would be acceptable if the pond at the WBG were drained in the future, thereby adding current sediment to the material to which direct contact soil exposures might occur. Exposures to child residents are slightly elevated and may be of concern.

7.4.5 Human Health Risk Summary

Table A.7.HHRA-25 summarizes the calculated cancer risks and non-cancer hazards for receptors at the WBG as currently characterized by soil, sediment, surface water, and fish tissue data. As shown in the table below, the total ELCR values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are below or within the benchmark range of 10^{-6} to 10^{-4} for cancer risk.

Summary of Calculated ELCRs and HIs for Receptor Exposure Scenarios

RECEPTOR/ EXPOSURE MEDIUM - SCENARIO	ELCR	HI
Site Worker		
Surface Soil - Direct Contact	1E-05	0.1
Sediment – Wading	2E-06	0.1
Surface Water – Wading	3E-06	0.2
TOTAL SITE RISKS (Site Worker):	**1E-05**	**0.4**
Hypothetical Future Construction Worker		
Combined Surface and Subsurface Soil - Direct Contact	5E-07	0.5
TOTAL SITE RISKS (Construction Worker):	**5E-07**	**0.5**
Hypothetical Future Adult Resident		
Combined Surface and Subsurface Soil - Direct Contact	-	0.2
Sediment – Wading	-	0.2
Surface Water – Wading	-	0.04
Fish Consumption	-	0.3
TOTAL SITE RISKS (Adult Resident):	**-**	**0.8**
Hypothetical Future Child Resident		
Combined Surface and Subsurface Soil - Direct Contact	-	2
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	-	–
Sediment – Wading	-	2
Surface Water – Wading	-	0.1
Fish Consumption	-	1
TOTAL SITE RISKS (Child Resident):	**-**	**6**
Hypothetical Future Resident (Adult and Child)		
Combined Surface and Subsurface Soil - Direct Contact	4E-05	-
Combined Surface and Subsurface Soil - Vapor Migration to Indoor Air	-	-
Sediment – Wading	1E-05	-
Surface Water – Wading	1E-06	-
Fish Consumption	NA	-
TOTAL SITE RISKS (Aggregate Resident):	**5E-05**	**-**
Hypothetical Future Adult Resident (Fishing Rodeo)		
Sediment - Wading	2E-07	0.009
Hypothetical Future Child Resident (Fishing Rodeo)		
Sediment - Wading	2E-07	0.08
Site Worker (Drained Pond)		
Combined Surface Soil and Sediment	1E-05	0.5
Hypothetical Future Construction Worker (Drained Pond)		
Combined Surface Soil and Sediment	6E-07	0.8
Hypothetical Future Adult Resident (Drained Pond)		
Combined Surface Soil and Sediment	1E-05	0.7
Hypothetical Future Child Resident (Drained Pond)		
Combined Surface Soil and Sediment	3E-05	6

The total HI values for all surface soil, combined surface and subsurface soil, sediment, and surface water exposures for each exposure scenario are equal to or below the benchmark of 1 for non-cancer hazard, with the exception of hypothetical future child resident exposure to combined surface and subsurface soil and exposure to sediment. When the HI for combined surface and subsurface soil is segregated into target site and critical effects, none of the hazards were greater than the benchmark of 1. When the HI for sediment is segregated into target site and critical effects, only the HIs associated with exposure to chromium are greater than the benchmark of 1.

Exposure to lead in soil by any of the receptors would not cause an elevated blood lead level to be predicted. When exposure to lead in soil and sediment was evaluated for the residential exposure scenarios, there were predicted elevated lead levels.

Summary of Estimated Blood Lead Levels for Receptor Exposure Scenarios

RECEPTOR	Estimated Blood Lead Level (µg/dL)		
	Adult	Child	Fetus
	50th percentile	Range	95th percentile
SOIL			
Hypothetical Future Construction Worker	2	–	7
SOIL AND SEDIMENT			
Site Worker	2	–	7
Hypothetical Future Child	–	2.9 – 5.5	–
Hypothetical Future Adult	2.8	–	10

Based on the results of the risk assessment, it is unlikely that industrial use of the property would result in adverse health effects. Likewise, no adverse effects would be expected for participants in the semi-annual fish rodeo. For the residential exposure scenarios, exposure to lead in sediments may pose an adverse health effect. Also, exposure to chromium in sediments may pose a slightly elevated hazard to children wading in surface water. Several (four) of the detections fell outside of the background chromium soil range. The maximum chromium sediment concentration of 15,400 mg/kg is well above the background range.

If the pond were drained in the future, it is unlikely that industrial or residential use of the property would result in adverse health effects with the exception of a slightly elevated hazard to children resulting from direct contact exposures to existing soils combined with sediment that would become soil.

7.5 Ecological Risk Assessment

The purpose of the ERA is to evaluate whether ecological receptors may be adversely impacted by exposure to site-related constituents detected in surface soil, sediment, surface water, and fish tissue at the WBG. The ERA approach is based on the Master Work Plan (URS 2003) in compliance with CERCLA/SARA and pursuant to RCRA Corrective Action requirements. The ERA was conducted in a manner consistent with USEPA guidance for ecological risk assessment (USEPA 2001a; 2000b; 1997c). This ERA is intended to provide input for risk management decision-making for the WBG, while maintaining a conservative approach protective of wildlife populations and communities. In accordance with USEPA guidance, the ERA for the WBG commenced with a SLERA and then concluded with BERA (USEPA 1997c).

This section summarizes the occurrence of constituents in each medium and identifies COPECs at the WBG for the ecological risk assessment; identifies the potential ecological exposure scenarios relevant to the WBG; and presents the estimated ecological risks associated with the identified COPECs and the relevant ecological exposure scenarios at the WBG. Methodologies for data summary and selection of COPECs, exposure assessment, and toxicity assessment for the ERA were presented in Section 2.4.

7.5.1 Selection of Constituents of Potential Ecological Concern

This section discusses the selection of COPECs for each medium. Risks to ecological receptors are calculated by dividing the exposure estimates (i.e., the maximum detected concentrations) by the conservative ESLs. The resulting ratio, the hazard quotient (HQ), is a highly conservative surrogate for the assessment endpoints identified in Section 2.4. HQs equal to or less than a value of 1 (to one significant figure) indicate that adverse ecological effects are unlikely (USEPA 1997c). HQs greater than 1 indicate that further evaluation is warranted. Therefore, the constituents with HQs greater than 1 are carried forward as COPECs into the BERA. Because the majority of the ESLs measure direct exposures and do not take into account exposures to upper trophic level species, chemicals identified as bioaccumulative were also carried forward as COPECs regardless of whether or not the associated HQ was greater than 1. Finally, as previously described, concentrations of inorganic constituents in soil were compared to background soil concentrations; those with concentrations below background were not considered as COPEC. The COPEC selection process for the WBG area are summarized in the subsections below.

7.5.1.1 Surface Soil

Surface soil COPECs were selected by comparing the analytical data with USEPA (2008c) EcoSSLs, USEPA (2003e) Region 5 ESLs, and ORNL values (Efroymson et al. 1997a,b) for surface soil. Table A.7.ERA-1 presents the selection of surface soil COPECs for the ERA. As summarized in Table A.7.ERA-1, 38constituents were identified as COPECs in surface soil as follows:

Six VOCs (acetone; carbon disulfide; d-limonene; methylene chloride; p-isopropyltoluene; and toluene) were detected in surface soil. HQs were less than or equal to 1 for acetone, carbon disulfide, methylene chloride, and toluene; however, ESLs were not available for d-limonene or p-isopropyltoluene and an HQ could not be calculated for these constituents. As a result, both d-limonene and p-isopropyltoluene were identified as COPECs in surface soil

Six SVOCs (bis[2-ethylhexyl]phthalate; carbazole; dibenzofuran; di-n-butylphthalate; di-n-octylphthalate; and n-nitrosodiphenylamine) were detected in surface soil. Four of these constituents had HQs less than or equal to 1; however, ESLs were not available for carbazole or dibenzofuran and so HQs could not be calculated for these constituents. As a result, both carbazole and dibenzofuran were identified as COPECs for surface soil.

Seventeen dioxin/furan compounds (1,2,3,4,6,7,8-HpCDD; 1,2,3,4,6,7,8-HpCDF; 1,2,3,4,7,8,9-HpCDF; 1,2,3,4,7,8-HxCDD; 1,2,3,4,7,8-HxCDF; 1,2,3,6,7,8-HxCDD; 1,2,3,6,7,8-HxCDF; 1,2,3,7,8,9-HxCDD; 1,2,3,7,8,9-HxCDF; 1,2,3,7,8-PeCDD; 1,2,3,7,8-PeCDF; 2,3,4,6,7,8-HxCDF; 2,3,4,7,8-PeCDF; 2,3,7,8-TCDD; 2,3,7,8-TCDF; OCDD; and OCDF) were detected in surface soil. Toxicity equivalency factors (TEFs) were used to evaluate the toxicity of each dioxin compound detected at the WBG. TEFs are weighted quantity measures that are based on the toxicity of each member of the dioxin and dioxin-like compound relative to the most toxic members of the category. In accordance with USEPA (USEPA 2003a) guidance, TEFs for the dioxin and dioxin-like compounds detected at the WBG were based on the relative toxicity with 2,3,7,8-TCDD and 1,2,3,7,8-PeCDD. The maximum concentrations for each dioxin and dioxin-like compound were multiplied by their corresponding TEF and then summed to get the dioxin toxicity equivalent, which was then compared to the available ESL. The dioxin toxicity equivalent had an HQ greater than 1, and as a result, was identified as a COPC for surface soil.

One explosive, pentaerythritol tetranitrate, was detected in surface soil. This constituent did not have an ESL and so an HQ could not be calculated. As a result, pentaerythritol tetranitrate was identified as a COPEC for surface soil.

Four herbicides (2,4,5-TP; 2,4-D; dalapon; and MCPP) were detected in surface soil. Both 2,4,5-TP and 2,4-D had an HQ of less than or equal to 1; however, an ESL was not available for dalapon or MCPP and so an HQ could not be calculated for these two constituents. As a result, both dalapon and MCPP were identified as COPECs in surface soil.

Two pesticides (4,4'-DDD and dieldrin) were detected in surface soil. Both of these constituents had an HQ less than or equal to 1, however, they were identified as bioaccumulative and as a result, were identified as COPECs for surface soil.

Seventeen PAHs (2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in surface soil. All of these constituents had an HQ of less than or equal to 1, however, all but 2-methylnaphthalene and naphthalene were identified as bioaccumulative and as a result, were identified as COPECs for surface soil.

One PCB, Aroclor 1254, was detected in surface soil. This constituent did not have an ESL and so an HQ could not be calculated. However, it was identified as bioaccumulative and identified as a COPEC for surface soil.

Twenty-three inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; silver; sodium; thallium; vanadium; and zinc) were detected in surface soil. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Fourteen of these constituents (antimony; arsenic; barium; cadmium; chromium; cobalt; copper; lead; manganese; mercury; selenium; thallium; vanadium; and zinc) had an HQ greater than 1, and two constituents (aluminum and iron) did not have an ESL available and so an HQ could not be calculated. However, five constituents (aluminum; cobalt; manganese; thallium; and vanadium) were detected below the background concentrations. In addition, silver was identified as bioaccmulative. As a result, antimony, arsenic, barium, cadmium, copper, chromium, iron, lead, mercury, selenium, silver, and zinc were identified as COPECs for surface soil.

7.5.1.2 Sediment

Sediment COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008d) Region 3 Sediment Screening Levels; ORNL values (Jones et al. 1997); and USEPA (2003e) Region 5 Ecological Screening Levels for sediment. Table A.7.ERA-2 presents the selection of sediment COPECs for the ERA, and 55 constituents were identified as COPECs in sediment as follows:

Five VOCs (2-butanone; acetone; carbon disulfide; methylene chloride; and toluene) were detected in sediment. Three of these constituents (2-butanone; acetone; and carbon disulfide) had an HQ greater than 1, and were identified as COPECs in sediment.

Seven SVOCs (1,2,4-trichlorobenzene; 1,4-dichlorobenzene; 4-methylphenol; bis[2-ethylhexyl]phthalate; carbazole; dibenzofuran; and phenol) were detected in sediment. Two of these constituents (4-methylphenol and bis[2-ethylhexyl]phthalate) had an HQ greater than 1. In addition, an ESL was not available for carbazole and the other two were considered bioaccumulative. As a result, all detected SVOCs except dibenzofuran and phenol were identified as COPECs for sediment.

Thirteen dioxin/furan compounds (1,2,3,4,6,7,8-HpCDD; 1,2,3,4,6,7,8-HpCDF; 1,2,3,4,7,8,9-HpCDF; 1,2,3,4,7,8-HxCDD; 1,2,3,4,7,8-HxCDF; 1,2,3,6,7,8-HxCDD; 1,2,3,6,7,8-HxCDF; 1,2,3,7,8,9-HxCDD; 2,3,4,6,7,8-HxCDF; 2,3,4,7,8-PeCDF; 2,3,7,8-TCDF; OCDD; and OCDF) were detected in sediment. TEFs were used to evaluate the toxicity of each dioxin compound detected in sediment at the WBG. The maximum concentrations for each dioxin and dioxin-like compound were multiplied by their corresponding TEF and then summed to get the dioxin toxicity equivalent, which was then compared to the available ESL. The dioxin toxicity equivalent had an HQ greater than 1, and as a result, was identified as a COPC for sediment.

Two explosives (1,3,5-trinitrobenzene and nitroglycerine) were detected in sediment. Neither of these constituents had an ESL and so an HQ could not be calculated. As a result, both 1,3,5-trinitrobenzene and nitroglycerine were identified as COPECs in sediment.

Four herbicides (2,4,5-T; 2,4-D; dicamba; and MCPP) were detected in sediment. Only 2,4-D had an HQ greater than 1. In addition, an ESL was not available for dicamba or MCPP and so an HQ could not be calculated for these two constituents. As a result, 2,4-D, dicamba, and MCPP were identified as COPECs in sediment.

Eleven pesticides (4,4'-DDD; 4,4'-DDE; 4,4'-DDT; delta-BHC; alpha-chlordane; gamma-chlordane; dieldrin; endosulfan II; endrin aldehyde; endrin ketone; and methoxyclor) were detected in sediment. Of these compounds, all but gamma-chlordane, endrin aldehyde, and endrin ketone either had HQs greater than 1 or were identified as bioaccumulative and therefore identified as COPEC.

Eighteen PAHs (1-methylnaphthalene; 2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[b]fluoranthene; benzo[g,h,i]perylene; benzo[k]fluoranthene; chrysene; dibenzo[a,h]anthracene; fluoranthene; fluorene; indeno[1,2,3-cd]pyrene; naphthalene; phenanthrene; and pyrene) were detected in sediment. All but two of these PAHs (1-methylnaphthalene and naphthalene) either had HQs greater than 1 or were identified as bioaccumulative and therefore identified as COPEC.

Twenty-three inorganics (aluminum; antimony; arsenic; barium; beryllium; cadmium; calcium; chromium; cobalt; copper; iron; lead; magnesium; manganese; mercury; nickel; potassium; selenium; silver; sodium; thallium; vanadium; and zinc) were detected in sediment. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Eleven of these constituents (antimony; arsenic; cadmium; chromium; cobalt; copper; iron; lead; manganese; silver; and zinc) had an HQ greater than 1. Those constituents identified as bioaccumulative or without screening levels also were selected as COPECs. Consequently, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, nickel, selenium, silver, thallium, vanadium, and zinc were identified as COPECs for sediment.

7.5.1.3 Surface Water

Surface water COPECs were selected by comparing the analytical data with ESLs from the following sources in order of priority: USEPA (2008c) Region 3 Surface Water Screening Levels; ORNL values (Suter and Tsao 1996); USEPA (2003e) Region 5 Ecological Screening Levels; and USEPA (2008e) Ambient Water Quality Criteria for surface water. Table A.7.ERA-3 presents the selection of surface water COPECs for the ERA, and 25 constituents were identified as COPECs in surface water as follows:

Eight VOCs (2-butanone; acetone; carbon disulfide; chloroform; cis-1,2-dichloroethene; tetrachloroethene; toluene; and trichloroethene) were detected in surface water. Only one of these detected constituents, chloroform, had an HQ greater than 1, and as a result, was identified as a COPEC for surface water.

Eight SVOCs (1,2-dichlorobenzene; 1,3-dichlorobenzene; 1,4-dichlorobenzene; benzoic acid; bis[2-ethylhexyl]phthalate; butylbenzylphthalate; diethylphthalate; and di-n-butylphthalate) were detected at concentrations in surface water. All of these constituents had an HQ less than or equal to 1, however, 1,2-dichlorobenzene; 1,3-dichlorobenzene; 1,4-dichlorobenzene were identified as bioaccumulative and were identified as COPECs for surface water.

One dioxin/furan compound, OCDD, was detected in surface water. TEFs were used to evaluate the toxicity of each dioxin compound detected in surface water at the WBG. The maximum concentration for this dioxin was multiplied by the corresponding TEF to get the dioxin toxicity equivalent, which was then compared to the available ESL. The dioxin toxicity equivalent had an HQ less than or equal to 1, however was identified as bioaccumulative and as a result, was identified as a COPC for surface water.

One explosive, m-nitrotoluene, was detected in surface water; however, this constituent had an HQ less than or equal to 1, and was not identified as a COPEC for surface water.

Two herbicides (2,4-D and MCPP) were detected in surface water. While 2,4-D had an HQ less than or equal to 1, an ESL was not available for MCPP and so an HQ could not be calculated for this constituent. As a result, MCPP was identified as a COPEC for surface water.

One pesticide, dieldrin, was detected in surface water. This constituent had an HQ less than or equal to 1 but was identified as bioaccumulative and was identified as a COPEC in surface water.

Seven PAHs (1-methylnaphthalene; 2-methylnaphthalene; acenaphthene; anthracene; fluorene; naphthalene; and phenanthrene) were detected in surface water. Only one of these constituents, anthracene, had an HQ greater than 1, however, acenaphthene, fluorine, and phenanthrene were also identified as bioaccumulative. Therefore four PAHs were identified as a COPEC for surface water.

Eighteen inorganics (aluminum; arsenic; barium; beryllium; calcium; copper; iron; lead; magnesium; manganese; nickel; potassium; selenium; silver; sodium; thallium; vanadium; and zinc) were detected in surface water. Four constituents are vital electrolytes and/or essential nutrients (i.e., calcium; magnesium; potassium; and sodium) and therefore were identified as non-toxic and not evaluated further. Ten of these detected constituents (aluminum; arsenic; barium; beryllium; copper; iron; lead; manganese; thallium; and vanadium) had an HQ greater than 1 and four (nickel;

selenium; silver; and zinc) were identified as bioaccumulative. As a result, aluminum, arsenic, barium, beryllium, copper, iron, lead,nickel, manganese, silver, selenium thallium, zinc, and vanadium were identified as COPECs for surface water.

One spring sample (WBG_SPRING001) was also evaluated for surface water COPECs by comparing the analytical data with background spring data as well as ESLs. As shown in the table below, one PAH and six inorganics were detected in the spring sample. Four of the inorganics are vital electrolytes and/or essential nutrients (calcium, magnesium, potassium, and sodium) and therefore were identified as non-toxic and not evaluated further. The remaining constituents detected in the spring sample were within or below the background concentrations or were below the corresponding ESL, and as a result, were not evaluated further.

Comparison of Detected Constituents in WBG Spring Sample to Background and ESLs

Constituent	ESL (µg/L)	Background Spring Data NSPRING003 09/24/08	Background Spring Data NSPRING004 09/24/08	WBG_SPRING001 09/24/08	Does Max Exceed ESL or BKG?

NT Non-toxic.

7.5.2 Summary of Selected Constituents of Potential Ecological Concern

Thirty-eight constituents were selected as COPECs in surface soil, fifty-five constituents were selected as COPECs in sediment, and twenty-five constituents were selected as COPECs in surface water because the HQs were greater than 1, the chemical was bioaccumulative, or an HQ couldn't be calculated because an ESL was not available.

7.5.3 Refinement of Risk Calculations for Direct Contact COPECs

The list of COPECs identified in the BERA was reevaluated by calculating refined HQs. The refined HQs were calculated for the COPECs identified in the SLERA using refined EPCs. Constituents identified as COPECs in the BERA that were bioaccumulative were carried forward into food chain models. The results of the recalculation of the HQs for the WBG are summarized in the subsections below.

7.5.3.1 Surface Soil

Thirty-eight COPECs in surface soil were carried forward into the BERA. When refined EPCs were compared with the ESLs, six constituents (PCDDs/PCDFs; antimony; chromium; copper; lead; and zinc) had a refined HQ greater than 1. In addition, ESLs were not available for 9 other constituents (d-limonene; p-isopropyltoluene; carbazole; dibenzofuran; pentaerythritol tetranitrate; dalapon; MCPP; Aroclor 1254; and iron). The BERA results for surface soil COPECs at the WBG are presented in Table A.7.ERA-4 and are discussed below:

Volatile Organic Compounds: Two VOCs (d-limonene and p-isopropyltoluene) were retained in the BERA because an ESL was not available and so HQs could not be calculated. These samples were each detected in only one sample at very low concentrations (i.e., < 1 mg/kg). Based on the low detected concentrations, adverse effects to wildlife due to potential VOC exposure are considered unlikely.

Semi-Volatile Organic Compounds: Two SVOCs (carbazole and dibenzofuran) were retained in the BERA because an ESL was not available and so HQs could not be calculated. These samples were each detected in less than 5 out of 78 samples at very low concentrations (i.e., < 1 mg/kg). Based on the low detected concentrations and limited occurrence, adverse effects to wildlife due to potential SVOC exposure is considered unlikely.

Dioxin/Furan Compounds: PCDDs and PCDFs and dioxin-like PCBs have a wide range of relative potencies and are usually found in complex mixtures in the environment. This makes determination of risk expensive and difficult. To simplify this process, internationally recognized toxic equivalency factors (TEFs) are used to evaluate their toxicity (Van den Berg et al. 1998). The TEF is an order of magnitude estimate of the toxicity of an individual congener relative to 2,3,7,8-TCDD. The congener concentration in the particular medium (e.g., soil, sediment) multiplied by the TEF yields the TEQ concentration (USEPA 2003f). It is assumed and generally supported in the literature, that effects from different PCDDs and PCDFs congeners are concentration additive (Van den Berg et al. 1998; Tillitt 1999).

The rationale for the use of TEQ approach is based on a common mechanism of action described for planar halogenated hydrocarbons (PHHs) including dioxins, furans and some PCBs. The intracellular target of PHHs is the aryl hydrocarbon receptor (AhR), which, while bound to the ligand, mediates the transactivation and inhibition of a variety of target genes. This activity results in a wide-array of responses with deleterious effects. The structure of a ligand is critical to its affinity for the AhR and the affinity of a particular ligand for the AhR correlates well with the resulting toxicity and biochemical responses (Safe 1990; 1998). Due to its high potency, the AhR mediated toxicity of 2,3,7,8-TCDD is considered the standard by which all other PHH potencies are normalized. The relative AhR-mediated toxicity of PHHs has been determined using a combination of in vitro and in vivo studies and TEFs are available for mammalian, avian and fish species (Van den Berg et al. 1998). For each individual PHH constituent, the exposure concentration is divided by the TEQ resulting in the HQ for that specific constituent. Given that PHHs act through a common mechanism of toxicity for common species, the individual HQs are summed to account for the cumulative risk from exposure to the dioxin/furan group as a whole. A cumulative HQ greater than 1 indicates that there is potential risk to ecological receptors. The TEQ approach is applied to the dioxin and furan compounds detected in surface soil, sediment, and surface water at the WBG.

USEPA Region 5 has ESL values for PCDFs (0.0000386 mg/kg) and for PCDDs (0.000000199 mg/kg). The maximum concentrations of the detected dioxin and furan compounds at the site exceed these ESL values, which indicate the potential for adverse effects to exposed terrestrial receptors. However, the ESLs were based on a food chain exposure to a masked shrew, which is a highly sensitive receptor. Furthermore, these criteria are not an indicator of direct toxicity to mammals and other terrestrial wildlife. When site-specific food chain modeling was evaluated for PCDFs/PCDDs, the HQs for the refined scenarios were below the benchmark value of 1 for both the short-tailed shrew (Table A.7.ERA-9) and the American robin (Table A.7.ERA-11). Based on these considerations, adverse impacts are not expected for wildlife exposed to PCDFs/PCDDs at the WBG area.

Explosives: One explosive, pentaerythritol tetranitrate, was retained in the BERA because an ESL was not available and so an HQ could not be calculated. This constituent was detected in only 1 of 20 surface soil samples, with a concentration of 0.11 mg/kg. Based on the low frequency of detection and low detected concentration, adverse effects to wildlife due to potential explosive exposure are considered unlikely.

Herbicides: Two herbicides (dalapon and MCPP) were retained in the BERA because an ESL was not available and so HQs could not be calculated. Dalapon was detected in 3 of 4 surface soil samples, at very low concentrations (i.e., < 1 mg/kg), and MCPP was detected in only 1 of 4 surface soil samples, at a relatively low concentration. Based on the low frequency of detection and low detected concentrations, adverse effects to wildlife due to potential herbicide exposure are considered unlikely.

<u>Polychlorinated Biphenyls</u>: One PCB, Aroclor 1254, was retained in the BERA because an ESL was not available and so an HQ could not be calculated. Aroclor 1254 was detected in 2 out of 28 surface soil samples with concentrations ranging from 0.03 mg/kg to 0.05 mg/kg.

While there are no Aroclor-specific ESLs from Region 5, Region 5 does provide an ESL of 0.000332 mg/kg for PCBs as a group. The maximum Aroclor 1254 concentration at the WBG is above this ESL; however, site-specific food chain modeling for the short-tailed shrew and American robin (Section 7.5.4), using conservative exposure assumptions, indicates that the potential risk from exposure to Aroclor 1254 at the WBG is very low. Based on these considerations and the limited occurrence in surface soil at the WBG area, adverse impacts are not expected for populations of ecological receptors exposed to Aroclor 1254 at the WBG.

<u>Inorganics</u>: Six inorganics (antimony; chromium; copper; iron; lead; and zinc) were retained in the BERA because the calculated HQ was above the benchmark of 1 or because an ESL was not available and so an HQ could not be calculated. These results are discussed below:

> <u>Antimony</u> – Antimony was detected in 26 out of 53 surface soil samples, with concentrations ranging from 0.29 mg/kg to 5.3 mg/kg. While all of these concentrations were above the ESL of 0.27 mg/kg, the calculated HQ was only slightly above the benchmark value of 1 (HQ=3). In addition, while site-specific background values for antimony were not available, these detected concentrations were compared to the mean background concentrations for antimony in surface soil of 1.2 mg/kg reported for Virginia (USEPA 2005b). The EPC for antimony at the WBG was 0.836 mg/kg, which was below the reported background soil concentration of antimony in Virginia. Consequently, adverse effects to wildlife exposed to antimony are unlikely given the similarity of detected concentrations with the state background value and the low calculated HQ.

Chromium – Chromium was detected in 56 out of 56 surface soil samples, with concentrations ranging from 22 mg/kg to 249 mg/kg. While all but five of these concentrations were above the ESL of 26 mg/kg, the calculated HQ was only slightly above the benchmark value of 1 (HQ=3). In addition, the calculated EPC for chromium was below the soil background value established at the site. Consequently, adverse effects to wildlife exposed to chromium are unlikely given similarity of detected concentrations with the site background value, and the low calculated HQ.

Copper – Copper was detected in 56 out of 56 surface soil samples, with concentrations ranging from 10.4 mg/kg to 1,340 mg/kg. While 22 concentrations were above the ESL of 28 mg/kg, only five of these concentrations were detected above the site background value. These five samples are bounded by samples that contain copper at background levels Figure 7-1), and it is estimated that the area that exceeds the background level is approximately 0.08 acre (3,675 ft^2) in size. This is a small area and as such is unlikely to represent a significant concern to ecological receptors. Consequently, adverse effects to wildlife exposed to copper are unlikely given the similarity of the majority of detected concentrations with the site background values and the limited spatial extent of the few samples with copper concentrations above the background level.

Iron – Iron was detected in 56 out of 56 surface soil samples, with concentrations ranging from 17,600 mg/kg to 54,000 mg/kg. While no ESL was available, only one of these concentrations was detected above the site background value, and all of the concentrations were within the range of background concentrations detected at the site. In addition, the calculated EPC for iron was below the soil background value established at the site. Consequently, adverse effects to wildlife exposed to iron are unlikely given the similarity of detected concentrations with the site background values.

Lead – Lead was detected in 56 out of 56 surface soil samples, with concentrations ranging from 11.6 mg/kg to 3,990 mg/kg. While all of these concentrations were above the ESL of 11 mg/kg, only eight of the concentrations were detected outside the range of background samples found at the site (Figure 7-1). These eight detections are encompassed within an approximately 0.8 acre (34,300 ft^2) and are unlikely to pose a significant adverse population-level impact to ecological receptors. Additionally, lead was further evaluated in the terrestrial food chain model.

Zinc – Zinc was detected in 56 out of 56 surface soil samples, with concentrations ranging from 15.2 mg/kg to 3,250 mg/kg. While 31 concentrations were above the ESL of 46 mg/kg, only five of the concentrations were above the range of background values detected at the site (Figure 7-1). The calculated EPC for zinc was below the maximum background concentration of zinc detected at the site. These eight detections are encompassed within an approximately 0.08 acre (3,675 ft^2) and are unlikely to pose a significant adverse population-level impact to ecological receptors at the site. Additionally, this COPEC was further evaluated in the terrestrial food chain model.

Twenty-six COPECs were also identified as bioaccumulative and were evaluated in the terrestrial food chain model.

7.5.3.2 Sediment

Fifty-five COPECs in sediment were carried forward into the BERA. When refined EPCs were compared with the ESLs, 27 constituents (2-butanone; acetone; carbon disulfide; 4-methylphenol; dioxin TEQ; 2,4-D; dieldrin; 2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[g,h,i]perylene; chrysene; dibenzo[a,h]anthracene; fluoranthene; indeno[1,2,3-cd]pyrene; phenanthrene; pyrene; chromium; copper; iron; lead; manganese; silver; and zinc), had a refined HQ greater than 1. In addition, ESLs were not available for nine other constituents (carbazole; 1,3,5-trinitrobenzene; nitroglycerine; dicamba; MCPP; barium; beryllium; thallium; and vanadium). The BERA results for sediment COPECs at the WBG are presented in Table A.7.ERA-5 and are discussed below:

Volatile Organic Compounds: Three VOCs (2-butanone; acetone; and carbon disulfide) were retained in the BERA because the calculated HQ was above the benchmark of 1. These results are discussed below:

2-Butanone – 2-Butanone was detected in 5 out of 14 sediment samples, with concentrations ranging from 0.015 mg/kg to 0.18 mg/kg. While three of these concentrations were above the ESL of 0.0424 mg/kg, the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). Based on these considerations, adverse effects to aquatic life due to potential 2-butanone exposure are considered unlikely.

Acetone – Acetone was detected in 11 out of 14 sediment samples, with concentrations ranging from 0.003 mg/kg to 0.23 mg/kg. While all but one of these concentrations were above the ESL of 0.0099 mg/kg, acetone is a common laboratory contaminant and was also detected in the laboratory blank. Consequently, adverse effects to aquatic life exposed to acetone are unlikely given the physical and chemical properties of the constituent (e.g., high vapor pressure; low Kow; and low potential for bioaccumulation) and the uncertainty that the VOC is a site-related constituent.

<u>Carbon disulfide</u> – Carbon disulfide was detected in 5 out of 12 sediment samples, with concentrations ranging from 0.0012 mg/kg to 0.0015 mg/kg. While all of these concentrations were above the ESL of 0.000851 mg/kg, the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). USEPA Region 5 has a sediment ESL of 0.0239 mg/kg, and the HQ calculated for the maximum detected concentration is less than 1. Based on these considerations, adverse effects to aquatic life exposed to carbon disulfide are unlikely given the low detected concentrations and low calculated HQs.

<u>Semi-Volatile Organic Compounds</u>: Two SVOCs (4-methylphenol and carbazole) were retained in the BERA because the calculated HQ was above the benchmark of 1 or because an ESL was not available and so an HQ could not be calculated. These results are discussed below:

<u>4-Methylphenol</u> – 4-Methylphenol was detected in 4 out of 17 sediment samples, with concentrations ranging from 0.13 mg/kg to 2.2 mg/kg. Only one of these concentrations was above the ESL of 0.67 mg/kg, and the calculated HQ was only slightly above the benchmark value of 1 (HQ=3). Consequently, adverse effects to aquatic life exposed to carbon disulfide are unlikely given the low frequency of detection and the low detected concentrations.

<u>Carbazole</u> – Carbazole was detected in 2 out of 15 sediment samples, with concentrations ranging from 0.14 mg/kg to 0.21 mg/kg. While no ESL was available for this constituent, adverse effects to aquatic life exposed to carbazole are unlikely given the low frequency of detection, the low detected concentrations.

<u>Herbicides</u>: Three herbicides (2,4-D; dicamba; and MCPP) were retained in the BERA because the calculated HQ was above the benchmark of 1 or because an ESL was not available and so an HQ could not be calculated. 2,4-D was detected in 2 of 5 sediment samples, both of which were located along an unnamed stream below the WBG pond, and an HQ of 5 was calculated using the maximum concentration. The remaining two herbicides, dicamba and MCPP, were each

detected in only 1 of 5 sediment samples, also at a location in the unnamed stream, about 70 ft downstream from the pond. ESLs were not available for these herbicides and so HQs could not be calculated. Based on these considerations, adverse effects to aquatic life exposed to herbicides are unlikely given the low frequency of detection and the low calculated HQ.

Polycyclic Aromatic Hydrocarbons: Thirteen PAHs (2-methylnaphthalene; acenaphthene; acenaphthylene; anthracene; benzo[a]anthracene; benzo[a]pyrene; benzo[g,h,i]perylene; chrysene; dibenzo[a,h]anthracene; fluoranthene; indeno[1,2,3-cd]pyrene; phenanthrene; and pyrene) were retained in the BERA because the calculated HQ were above the benchmark of 1. Calculated HQs for these PAHs ranged from 2 to 50. As described in Section 2.4.2.4.1.4, since PAHs were COPECs in this ERA, the ESBTU approach was used to calculate a total TU which was compared to the benchmark of 1, as seen in Table A.7.ERA-6. TOC ranged between 2.2% to 5.4% at the site and averaged at 3.4%. As previously discussed, a default UF of 2.75 was applied to the total TU to obtain an accurate estimation of 50% confidence. The PAH TUs for all of the sediment samples collected from the pond at the WBG are less than 1, which means the potential for PAHs in the pond sediment to cause adverse effects to benthos (bottom dwelling aquatic organisms) is unlikely. Only 1 of the sediment samples collected from the WBG area had a PAH TU greater than 1, and that was for sample WBGSW/SD09, with a TU of 4 (Figure 7-2). This sample was collected from the unnamed stream, at a location approximately 300 ft downstream of the pond. There is another sediment sample location very close in proximity to the SD09 sample, and it is WBG-SE006; the PAH TU for this sample is less than 1 (0.07). In addition to WBG-SE006, there are 4 other sediment samples between WBGSW/SD09 and the pond, and their sample IDs are WBG-SE005, WBGSW/SD13, WBGSW/SD008, and WBGSD1. The PAH TUs for all of these locations are less than 1. Additionally, the nearest downstream sample from WBGSW/SD09 is RYSW/SD12 and the PAH TU for that location is less than 1 (0.2). Therefore, the available data suggests that the extent of sediment containing PAHs at concentrations that may present a hazard to benthic invertebrates is limited to one location (i.e., WGBSW/SD09) in the unnamed stream. No PAHs were detected in the surface water sample collected from this location. Based on these considerations, the potential for PAHs to represent a hazard to aquatic life in the WBG pond is very low, and in the unnamed stream any potential adverse effect would be limited to the immediate area near WBGSW/SD09.

Inorganics: Eleven inorganics (barium; beryllium; chromium; copper; iron; lead; manganese; silver; thallium; vanadium; and zinc) were retained in the BERA because the calculated HQ was above the benchmark of 1 or because an ESL was not available and so an HQ could not be calculated. These results are discussed below:

Barium – Barium was detected in 28 out of 28 sediment samples, with concentrations ranging from 32.3 mg/kg to 179 mg/kg. While no screening value was available for barium and no background sediment data was collected, all of these detected concentrations were below the soil background value established at the site. Consequently, adverse effects to aquatic life exposed to barium are unlikely given the similarity of detected concentrations with the site background value.

Beryllium – Beryllium was detected in 27 out of 28 sediment samples, with concentrations ranging from 0.45 mg/kg to 2.27 mg/kg. While no screening value was available for beryllium and no background sediment data was collected, all of these detected concentrations were within the range of detected soil background values at the site. Consequently, adverse effects to aquatic life exposed to beryllium are unlikely given the similarity of detected concentrations with the range of site background values.

Chromium – Chromium was detected in 28 out of 28 sediment samples, with concentrations ranging from 5.17 mg/kg to 15,400 mg/kg. While nine of these concentrations were above the ESL of 43.4 mg/kg, and no background sediment data was collected, only three of the detected concentrations were above the range of detected soil background values at the site. All nine samples above the ESL were located along the northern edge of the pond at the WBG (Figure 7-3). Five of these samples (WBGSD17, WBGSD18, WBGSD22, WBGSD23, and WBGSW/SD10) were all located within a 3,675 ft^2 area (roughly 0.08 acre), and were surrounded by samples with chromium concentrations below the ESL of 43.4 mg/kg. The remaining four samples were spread along the northern edge of the pond and could potentially cause adverse effects to sediment dwelling organisms if chronic exposure occurs to the elevated concentrations of chromium at the WBG.

Copper – Copper was detected in 28 out of 28 sediment samples, with concentrations ranging from 6.36 mg/kg to 188 mg/kg. Three of these concentrations were above the ESL of 31.6 mg/kg, and while no background sediment data was collected, all but two of the detected concentrations were below the established soil background value. In addition, the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). Consequently, adverse effects to aquatic life exposed to copper are unlikely given the similarity of detected concentrations with the soil background value, and the low calculated HQ.

Iron – Iron was detected in 28 out of 28 sediment samples, with concentrations ranging from 8,530 mg/kg to 293,000 mg/kg. Twelve concentrations were above the ESL of 20,000 mg/kg, and while no background sediment data was collected, all but one of these detected concentrations were below the soil background value established at the site. In addition, the calculated HQ for the maximum concentration was only slightly above the benchmark value of 1 (HQ=4). Consequently, adverse effects to aquatic life exposed to iron are unlikely given the similarity of detected concentrations with the soil background value, and the low calculated HQ.

Lead – Lead was detected in 32 out of 32 sediment samples, with concentrations ranging from 5.61 mg/kg to 109,000 mg/kg. While 19 of these concentrations were above the ESL of 35.8 mg/kg, and no background sediment data was collected, only 8 detected concentrations were outside the range of soil background concentrations (2.1 mg/kg to 256 mg/kg) reported at the site. All but one of these concentrations were located within a 2,450 ft2 area (approximately 0.06 acre) along the northern edge of the pond at the WBG (Figure 7-3). In addition, the maximum detected concentration of 109,000 mg/kg was surrounded by samples below the ESL of 35.8 mg/kg, and this area encompasses approximately 0.06 acre (2,450 ft^2). While it is possible that adverse effects might occur to benthic organisms exposed to this elevated lead concentration, the potential for lead to represent a significant and widespread ecological hazard in the pond is unlikely due to the localized and small spatial extent. Overall, significant adverse effects to aquatic life exposed to lead are unlikely given the similarity of the majority of detected concentrations with the range of site background values, and the limited spatial extent of affected sediments. Additionally, lead was further evaluated in the aquatic food chain model.

Manganese – Manganese was detected in 28 out of 28 sediment samples, with concentrations ranging from 25.9 mg/kg to 2,310 mg/kg. While five of these concentrations were above the ESL of 460 mg/kg, and no background sediment data was collected, all of the detected concentrations were below the established soil background value. In addition, the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). Consequently, adverse effects to aquatic life exposed to manganese are unlikely given the similarity of detected concentrations with the soil background value, and the low calculated HQ.

Silver – Silver was detected in 4 out of 26 sediment samples, with concentrations ranging from 0.79 mg/kg to 8.42 mg/kg. Only two of these concentrations were above the ESL of 1 mg/kg, which were both located on the northern edge of the pond, and the refined HQ of 8 was calculated using the maximum concentration. Based on the limited occurrence of silver and the relatively low calculated HQ, adverse effects to aquatic life exposed to silver are unlikely. Additionally, silver was further evaluated in the aquatic food chain model.

Thallium – Thallium was detected in 12 out of 28 sediment samples, with concentrations ranging from 0.1 mg/kg to 1.7 mg/kg. While no screening value was available for thallium and no background sediment data was collected, all of these detected concentrations were below the established soil background value at the site. Consequently, adverse effects to aquatic life exposed to thallium are unlikely given the similarity of detected concentrations with the site background value.

Vanadium –Vanadium was detected in 28 out of 28 sediment samples, with concentrations ranging from 14 mg/kg to 106 mg/kg. While no screening value was available for vanadium and no background sediment data was collected, all of these detected concentrations were below the established soil background value at the site. Consequently, adverse effects to aquatic life exposed to vanadium are unlikely given the similarity of detected concentrations with the site background value.

Zinc – Zinc was detected in 28 out of 28 sediment samples, with concentrations ranging from 17.1 mg/kg to 17,300 mg/kg. While three of these concentrations located at the pond were above the ESL of 121 mg/kg, only one concentration was detected above the range of detected soil background values at the site. In addition, the maximum concentration was surrounded by samples with zinc below the ESL (Figure 7-3). Based on this information, the spatial extent of affected sediment is limited in size and not expected to represent a significant ecological concern. Additionally, zinc was further evaluated in the aquatic food chain model.

Thirty-four constituents were identified as bioaccumulative and were evaluated in the aquatic food chain model.

7.5.3.3 Surface Water

Twenty-five COPECs in surface water were carried forward into the BERA. When refined EPCs were compared with the ESLs, 10 constituents (anthracene; aluminum; arsenic; barium; beryllium; copper; iron; lead; manganese; and thallium) had a refined HQ greater than 1. In addition, an ESLs was not available for MCPP. The BERA results for surface water COPECs at the WBG are presented in Table A.7.ERA-7 and are discussed below:

Herbicides: One herbicide, MCPP, was retained in the BERA because an ESL was not available and so an HQ could not be calculated. This COPEC was detected in only 1 of 5 samples, at a very low concentration (i.e., < 0.1 mg/kg). Based on these considerations, adverse effects to aquatic life potentially exposed to MCPP are unlikely.

Polycyclic Aromatic Hydrocarbons: One PAH, anthracene, as retained in the BERA because the calculated HQ was greater than the benchmark value of 1. This COPEC was detected in only 2 of the 15 surface water samples, with a calculated HQ that was only slightly above the benchmark of 1 (HQ=3). Consequently, adverse effects to aquatic life exposed to this PAH are unlikely given the limited occurrence and low calculated HQ.

Inorganics: Nine inorganics (aluminum; arsenic; barium; beryllium; copper; iron; lead; manganese; and silver) were retained in the BERA because the calculated HQs were greater than the benchmark value of 1. These results are discussed below:

Aluminum – Aluminum was detected in 13 out of 13 surface water samples, with concentrations ranging from 0.0392 mg/ L to 0.811 mg/L. While all of these concentrations were above the ESL of 0.087 mg/L, the calculated HQ was only slightly above the benchmark value of 1 (HQ=4). Furthermore, the ESL used is from USEPA (2008c) Region 3 and is based on a water quality criterion protective of salmonids (i.e., coldwater habitat species of fish such as trout and salmon) which is likely overly conservative for the type of warmwater habitat (and associated aquatic species) that is prevalent in this locale. When an alternative screening value of 0.46 mg/L from Sample et al. 1996 was used, an HQ of less than 1 was calculated. This alternative screening value is based on the lowest chronic value of aquatic life, and is considered to be a more representative screening value for aluminum at the WBG than the Region 3

ESL. Based on these considerations, adverse effects to aquatic life exposed to aluminum are unlikely.

Arsenic – Arsenic was detected in 2 out of 13 surface water samples, with concentrations ranging from 0.0086 mg/ L to 0.0104 mg/L. While both of these concentrations were above the ESL of 0.005 mg/L, the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). Consequently, adverse effects to aquatic life exposed to arsenic are unlikely given the limited occurrence and the low calculated HQ. Additionally, arsenic was further evaluated in the aquatic food chain model.

Barium – Barium was detected in 13 out of 13 surface water samples, with concentrations ranging from 0.054 mg/L to 0.148 mg/L. While all of these samples were greater than the ESL of 0.004 mg/L, the ESL used from USEPA (2008c) Region 3 was based on a secondary chronic value from Suter et al. 1996a, and was established using an extremely limited dataset. An alternative aquatic ESL of 0.22 mg/L from USEPA (2003e) Region 5 was found, which is considered to be a more representative screening value. When this ESL was used, an HQ of less than 1 was calculated. Based on these considerations, adverse effects to aquatic life exposed to barium are unlikely.

Beryllium – Beryllium was detected in 1 out of 13 surface water samples, with a concentration of 0.0011 mg/L. Although this concentration was above the ESL of 0.00066 mg/L, the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). Additionally, when an alternative ESL of 0.0036 mg/L from USEPA (2003e) Region 5 was used, an HQ of less than 1 was calculated. Based on these considerations, adverse effects to aquatic life exposed to beryllium are unlikely.

Copper – Copper was detected in 6 out of 13 surface water samples, with concentrations ranging from 0.0011 mg/L to 0.0235 mg/L. Only four of these concentrations were above than the ESL of 0.009 mg/L, and the calculated HQ was only slightly above the benchmark value of 1 (HQ=2). In addition, this ESL is based on a default hardness value of 100 mg/L. A site-specific hardness value of 251 mg/L (average at the WBG area) was used to calculate an ESL of 0.01966 mg/L. When this ESL was used, an HQ of less than 1 was calculated. Based on these considerations, adverse effects to aquatic life exposed to copper are unlikely given the low calculated HQs. Additionally, copper was further evaluated in the aquatic food chain model.

Iron – Iron was detected in 14 out of 15 surface water samples, with concentrations ranging from 0.0416 mg/L to 50.9 mg/L. While six of these concentrations were greater than the ESL of 0.3 mg/L, as previously stated, the surface water samples were not filtered, and as such the results represent total iron. Therefore, it is not known what portion, if any, of the iron is in the dissolved (i.e., filtered) form. It is possible that even though the total iron concentrations exceed the ESL, the dissolved (and therefore bioavailable) iron concentrations may in actuality not exceed the ESL. Based on these considerations, adverse effects to aquatic life exposed to iron may not occur.

Lead – Lead was detected in 11 out of 18 surface water samples, with concentrations ranging from 0.00017 mg/L to 0.106 mg/L. Only five of these concentrations were above than the ESL of 0.0025 mg/L, which was based on a default hardness value of 100 mg/L. A site-specific hardness value of 251 mg/L (average at the WBG area) was used to calculate an ESL of 0.044 mg/L. When the ESL of 0.044 mg/L was used along with the EPC of 0.0248 mg/L, an HQ of less than 1 was calculated. Consequently, adverse effects to wildlife exposed to lead are unlikely when using site-specific ESLs. Additionally, lead was further evaluated in the aquatic food chain model.

Manganese – Manganese was detected in 14 out of 15 surface water samples, with concentrations ranging from 0.002 mg/ L to 1.47 mg/L. Only one of these concentrations was above than the ESL of 0.12 mg/L. In addition, as previously stated the surface water samples were not filtered, and as such the results represent total manganese. Therefore, it is not known what portion, if any, of the manganese is in the dissolved (i.e., filtered) form. It is possible that even though the total manganese concentrations exceed the ESL, the dissolved (and therefore bioavailable) manganese concentrations may in actuality not exceed the ESL. Based on these considerations, adverse effects to wildlife exposed to manganese are unlikely.

Thallium – Thallium was detected in 2 out of 13 surface water samples, with concentrations ranging from 0.0023 mg/L to 0.0054 mg/L. While both concentrations were above the ESL of 0.0008 mg/L, the ESL used from USEPA (2008c) Region 3 was based on a Canadian Water Quality value. When an alternative ESL of 0.01 mg/L from USEPA (2005e) Region 5 was used, an HQ of less than 1 was calculated. This alternative screening value is based on a Tier II Michigan water quality value established using a robust set of toxicological data for aquatic life. This value is considered to be a more representative screening value for thallium. Based on these considerations and the low frequency of detection, adverse effects to aquatic life exposed to thallium are unlikely.

Twelve COPECs were also identified as bioaccumulative and were evaluated in the aquatic food chain model.

7.5.4 Refinement of Assessment and Measurement Endpoints for Bioaccumulative COPECs

Food chain modeling was conducted at the WBG in order to evaluate the potential ecological effects of the bioaccumulative COPEC in soil, sediment, and surface water on the receptors identified in Section 2.4. COPECs identified in soil were evaluated in the terrestrial food chain, and COPECs identified in sediment and surface water were evaluated in the aquatic food chain. The results for both the maximum and refined scenarios of these models are presented in Tables A.7.ERA-8 through A.7.ERA-15, and the results of each of the refined scenarios are discussed in the subsections below.

7.5.4.1 Terrestrial Food chain Model

As summarized in Table A.7.ERA-16, the refined scenario NOAEL HQs and LOAEL HQs for the short-tailed shrew (Tables A.7.ERA-8 and A.7.ERA-9) were less than 1 for all of the bioaccumulative COPECs, with the exception of dibenzo(a,h)anthracene and zinc. The dibenzo(a,h)anthracenen NOAEL HQ was 4 and the LOAEL HQ was 0.4 and the zinc NOAEL HQ was 8 and the LOAEL was 0.8. The NOAEL is a very conservative screening criterion while the LOAEL indicates a concentration above which adverse impacts to individual mammals and birds may occur. For the American robin (Tables A.7.ERA-10 and A.7.ERA-11), the refined scenario NOAEL HQs and LOAEL HQs were less than 1 for all of the bioaccumulative COPECs, with the exception of lead. The NOAEL and LOAEL HQs for lead were 3 and 0.3, respectively. When it is considered that the NOAEL is a very conservative toxicity screening value, and the HQs for the more realistic LOAEL are less than 1, then these results indicate that individual short-tailed shrews and American robins (or other insectivorous mammals and birds) exposed to these COPECs are not expected to experience adverse effects.

Based on the overall analysis of terrestrial food chain modeling HQs and consideration of the limited spatial extent of impacted soils, adverse effects are not expected for short-tailed shrews (and other insectivorous mammals) and American robins (and other insectivorous birds) populations exposed to bioaccumulative COPECs in soil at the WBG.

7.5.4.2 Aquatic Food chain Model

As summarized in Table A.7.ERA-17, the refined scenario NOAEL HQs and LOAEL HQs for both the mink (Tables A.7.ERA-12 and A.7.ERA-13) and the great blue heron (Tables A.7.ERA-14 and A.7.ERA-15) were less than or equal to 1 for all 34 of the bioaccumulative COPECs identified in sediment and/or surface water.

7.5.5 Ecological Risk Summary

Screening-level and baseline risk assessments were completed for the WBG. After the SLERA, 38 constituents were selected as COPECs in surface soil, 55 constituents were selected as COPECs in sediment, and 25constituents were selected as COPECs in surface water because the HQs were greater than 1 or an HQ could not be calculated because an ESL was not available. After the BERA, 36 constituents in surface soil, 52 constituents in sediment, and 23 constituents in surface water were retained because the HQs were greater than 1, the chemical was bioaccumulative or an HQ could not be calculated because an ESL was not available. Food chain modeling was evaluated for all those constituents identified as bioaccumulative.

Tables A.7.ERA-16 and A.7.ERA-17 summarize the constituents in surface soil, sediment, and surface water carried through the BERA and evaluated in the terrestrial and/or aquatic food chain model. As shown in Table A.7.ERA-16, the refined scenario NOAEL HQ for zinc was greater than 1 for the short-tailed shrew, and the refined scenario NOAEL HQs for lead and zinc were greater than 1 for the American robin. While the potential does exist for unacceptable risk to individual insectivorous mammals and birds exposed to surface soils containing affected concentrations of these COPECs, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents in surface soil, the potential for population-level effects are low.

As shown in Table A.7.ERA-17, the refined scenario NOAEL HQ for the mink and great blue heron were all below 1, indicating no risk to piscivorous species. Based on the overall analysis of aquatic food chain modeling HQs, adverse effects are not expected for aquatic life exposed to bioaccumulative COPECs in sediment and/or surface water at the WBG,.

7.6 WBG Summary and Conclusions

The WBG was formerly used as a burning ground to decontaminate explosives contaminated material and to dispose of excess and off-spec explosives/energetics

Western Burning Ground

during historical site operations. The main burn area was approximately 170 ft long by 100 ft wide and is surrounded on three sides by an approximately 4 ft high earthen berm. A dirt road runs parallel to the open side of the former burn area, leading north to Alger Road, and south to the top of a steep slope above an unnamed pond. The dirt road was reportedly constructed on top of an ashy layer of material extending from the burning ground at the time of the pond construction. The pond was constructed during the early 1990s and is fed by Wiggins Spring at the northwest (upgradient) end of the pond. The pond also collects runoff from the surrounding area through a series of storm water ditches/culverts. The WBG is no longer active.

The HHRA evaluated potential current exposure of site workers to surface soil, surface water, and sediment, potential future exposures of construction workers to total soil and potential future residential exposure to total soil, surface water, sediment, and fish caught in the pond at the WBG. In addition, the HHRA evaluated potential exposures to participants in the semi-annual fish rodeo and exposures to hypothetical workers and hypothetical residents under future conditions if the pond were drained. The soil, sediment, and surface water COPCs were evaluated for direct contact.

A current or future site worker could be present at the WBG area, and could be exposed to surface soil, sediment, or surface water. The total cumulative ELCR for site workers exposed to surface soil, sediment, and surface water at the WBG is 1×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.4, which is less than the benchmark of 1. The projected blood lead levels were below the benchmark of 10 µg/dL.

A hypothetical future construction worker could be present at the WBG area, and could be exposed to combined surface and subsurface soil. The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the WBG was 5×10^{-7}, which is below the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is 0.5, which is less than the benchmark of 1. The projected blood lead levels were below the benchmark of 10 µg/dL.

A hypothetical future resident could be present at the WBG area, and could be exposed to combined surface and subsurface soil, sediment, or surface water. The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water at the WBG is 5×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future adult residents is 0.8, which is below the benchmark of 1. Exposure to lead in soil and sediment was evaluated and this exposure could cause elevated blood lead levels. Exposure to lead in sediments, although intermittent in nature, contributed to the elevated blood lead levels.

The total cumulative HI for hypothetical future child residents is 6, which is above the benchmark of 1. When the HIs were segregated by target site and critical effects, only exposure to chromium in sediments resulted in an HI greater than 1. None of the other HIs were greater than 1. Blood lead level estimates for the hypothetical child resident receptor from exposure to lead in soil and sediment could result in an elevated blood lead level based on a cumulative exposure. This elevated blood lead level was due to the contribution of sediments to the overall exposure. Exposure to lead in soil was not likely to cause elevated blood lead levels.

The total cumulative ELCRs for hypothetical future site workers, construction workers, and residents under future conditions were the pond to be drained were all below or within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The only total cumulative HI that exceeded the benchmark of 1 was for the hypothetical future child resident. When the HIs were segregated by target site and critical effects, only exposure to chromium in sediments resulted in an HI greater than 1. None of the other HIs were greater than 1.

Based on the results of the risk assessment, it is unlikely that industrial use of the property would result in adverse health effects. For the residential exposure scenarios, exposure to lead in sediments may pose an adverse health effect. Also, exposure to chromium in sediments may pose a slightly elevated hazard to children wading in surface water. The maximum chromium sediment concentration of 15,400 mg/kg is well above the background range.

A SLERA and BERA were completed for the WBG, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial food chain model indicate that while some of the NOAEL and LOAEL HQs were greater than 1, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, adverse effects of these COPECs at the population-level are unlikely at the WBG.

Similarly, the results of the sediment and surface water evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the aquatic food chain model indicate adverse effects are not expected for aquatic life exposed to bioaccumulative COPECs in sediment and/or surface water at the WBG.

8. RFAAP-NRU Groundwater

Groundwater at the RFAAP-NRU is considered to be a facility-wide resource, rather than specific to any of the individual Study Areas. Therefore, the groundwater investigation activities performed at the RFAAP-NRU will be discussed on a facility-wide basis. This section presents the human health and ecological risk assessments for groundwater.

8.1 Risk Assessment Datasets

Data generated from the site characterization activities were used in the risk assessment. The groundwater risk assessment dataset was prepared then summarized and statistically analyzed per methods described in Section 2.2. Table A.8.HHRA-1 presents the groundwater risk assessment dataset summary highlighting the number of detects, number of samples, FOD, minimum and maximum detected concentrations, minimum and maximum detection limits, and EPCs.

The groundwater dataset included data collected from the springs and the groundwater monitoring wells. While the spring samples were evaluated for both human health and ecological risk, the remaining groundwater samples were only evaluated for human health risk, as exposure to groundwater by ecological receptors is unlikely. The ecological risks for the spring samples collected at the RY and the WBG were evaluated as part of the surface water data sets collected at those sites, and are discussed in Sections 6 and 7, respectively. Due to the Karst formation, the presence of colloidal particles measured as turbidity in the groundwater samples resulted in elevated levels of trace metals. This was evidenced by the 2007 groundwater inorganic data. Therefore, a supplemental round of groundwater samples was collected in 2008 and analyzed for metals using low flow techniques to replace the 2007 inorganic data. An additional round of groundwater samples was collected in March 2010. Among these sampling events, adequate data were available to exclusively use inorganic data from filtered samples for assessing risk through exposure to dissolved phase inorganic constituents in groundwater used as a potable water supply.

8.2 Human Health Risk Assessment

The purpose of this risk assessment is to evaluate the potential current and future risks and hazards to human health associated with potential exposure to constituents detected in groundwater samples collected at the RFAAP-NRU. The risk assessment approach follows the approach outlined in the Radford Army Ammunition Plant Final

Master Work Plan (URS 2003) which is based on USEPA guidance for risk assessments (USEPA 2004a; 2000a; 1997a; 1992; 1991a; 1989).

This section summarizes the occurrence of constituents in groundwater and identifies groundwater and presents the estimated human health risks associated the relevant human exposure scenarios. The methodologies for the selection of COPCs, the exposure assessment, and the toxicity assessment for the HHRA are presented in Section 2.2.

8.2.1 Selection of Constituents of Potential Concern

Groundwater COPCs were selected by comparing the analytical data with USEPA (2009a) adjusted tap-water RSLs. Table A.8.HHRA-2 presents the selection of groundwater COPCs for the HHRA. Chloroform and dioxin/furan compounds were the only organic constituents that were identified as groundwater COPCs. Two explosive compounds were also detected and selected as COPCs. Several inorganic constituents were also identified as COPCs as discussed below.

Three VOCs (acetone, chloroform, and toluene) were detected in groundwater. Only chloroform was detected in concentrations above the USEPA (2009a) tap water RSL. As a result, only chloroform was identified as a groundwater COPC.

Seventeen dioxin/furan compounds (1,2,3,4,6,7,8-HpCDD; 1,2,3,4,6,7,8-HpCDF; 1,2,3,4,7,8,9-HpCDF; 1,2,3,4,7,8-HxCDD; 1,2,3,4,7,8-HxCDF; 1,2,3,6,7,8-HxCDD; 1,2,3,6,7,8-HxCDF; 1,2,3,7,8,9-HxCDD; 1,2,3,7,8,9-HxCDF; 1,2,3,7,8-PeCDD; 1,2,3,7,8-PeCDF; 2,3,4,6,7,8-HxCDF; 2,3,4,7,8-PeCDF; 2,3,7,8-TCDD; 2,3,7,8-TCDF; OCDD; and OCDF) were detected in groundwater. Ten of these constituents (11,2,3,4,7,8-HxCDD; 1,2,3,4,7,8-HxCDF; 1,2,3,6,7,8-HxCDF; 1,2,3,7,8,9-HxCDD; 1,2,3,7,8,9-HxCDF; 1,2,3,7,8-PeCDD; 1,2,3,7,8-PeCDF; 2,3,4,7,8-PeCDF; 2,3,7,8-TCDD; and 2,3,7,8-TCDF) were detected above the USEPA (2009a) tap water RSL values, and as a result, were identified as COPCs for groundwater.

Three explosives, nitrobenzene, pentaerythritol tetranitrate, and perchlorate, were detected in groundwater. Perchlorate was detected at concentrations below the USEPA (2009a) tap water RSL, and as a result, was not selected as a COPC for groundwater. Nitrobenzene was detected above the tapwater RSL, and thus was included as a COPC. Pentaerythritol tetranitrate was also detected; it was retained as a COPC based on the lack of a tapwater RSL.

Groundwater

Two PAHs (naphthalene and phenanthrene) were detected in groundwater. Both of these constituents were detected at concentrations below the adjusted tap water RSLs, and as a result, were not selected as COPCs for groundwater.

Fourteen inorganic constituents were detected in the groundwater samples namely: aluminum; arsenic; barium; calcium; chromium; cobalt; copper; iron; magnesium; manganese; nickel; potassium; sodium; and zinc. Four of these constituents (calcium; magnesium; potassium; and sodium) are essential nutrients and are not identified as groundwater COPCs. Maximum concentrations of threeother inorganic constituents (arsenic; iron; and manganese) in filtered groundwater samples exceeded the USEPA (2009a) tap water RSLs and were therefore identified as COPCs for groundwater.

8.2.2 Determination of Exposure Point Concentrations

Fifteen constituents were selected as COPCs in groundwater based on data from the groundwater samples because they were present at maximum concentrations that were above the adjusted tap-water RSL values. The distribution testing and UCL calculations were performed as described in Section 2.2.6.1, and the EPCs for these COPCs are summarized in Table A.8.HHRA-3.

8.2.3 Human Health Risk Characterization

Groundwater exposure pathways include direct contact pathways when groundwater is used as a potable water supply and inhalation of vapors from groundwater. The inhalation pathway is complete under two scenarios. Vapors can occur in ambient air from water used as a potable water supply (e.g., during residential showering). Vapors can also be present in indoor air through subsurface vapor intrusion into buildings.

The physical and chemical properties and toxicity values used to evaluate excess lifetime cancer risks and non-cancer hazards are presented in Tables A.2-3 through A.2-9. The exposure assumptions used to evaluate potentially exposed receptors are presented in Table A.2-10. The equations used in the risk characterization calculations are presented in Table A.2-15.

The excess lifetime cancer risks and non-cancer hazards for each potentially exposed receptor included in the risk assessment for the RFAAP-NRU are discussed in the subsections below.

Groundwater

8.2.3.1 Site Worker

Risks to commercial/industrial receptors (site workers) exposed to groundwater as a potable source at the NRU is not expected to occur and the current land use associated with the site is not expected to change. As a result, future use of the site groundwater as a potable source for industrial purposes is considered unlikely, but was considered as a conservative measure. Risks were estimated for all COPCs. Risks to commercial/industrial receptors exposed to vapors indoors due to subsurface vapor intrusion were assessed using the USEPA vapor intrusion model.

The ELCR and non-cancer hazard index for site worker exposure to ingestion and dermal contact with groundwater are presented in Table A.8.HHRA-6 and summarized in Table A.8.HHRA-7. The ELCR for groundwater is within the USEPA target risk range, and the HI is below the benchmark value of 1. Model outputs for the vapor intrusion evaluation are presented in Table A.8.HHRA-10. The ELCR for a site worker from exposure to vapors in indoor air due to subsurface vapor intrusion was 2×10^{-8} which is well below the target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative ELCR for site worker exposed to groundwater, presented in Table A.8.HHRA-4, is 4×10^{-5}, which is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is 0.4, which is below the benchmark of 1.

8.2.3.2 Hypothetical Future Residents

Residential development of the NRU is not expected to occur and the current land use associated with the site is not expected to change. As a result, future use of the site for residential purposes is considered unlikely, but was considered as a conservative measure. Risk to the potential future resident receptor from exposure to groundwater was evaluated. Risks were estimated for all COPCs. For inorganic COPCs, risks were calculated using EPCs based on the filtered groundwater samples.

The ELCRs and non-cancer hazard index for hypothetical future residential exposure to groundwater through the direct ingestion exposure pathway are presented in Tables A.8.HHRA-4 and A.8.HHRA-5, and are summarized in Table A.8.HHRA-7. Exposure of the hypothetical future adult and child resident was also evaluated for the vapor intrusion pathway. The results are summarized in Tables A.8.HHRA-8 and A.8.HHRA-9 and are discussed below.

The total cumulative ELCR for hypothetical future residents exposed to groundwater, presented in Table A.8.HHRA-4, is 2×10^{-4}, which is slightly above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future adult residents is 0.6, which is below the benchmark of 1. The total cumulative HI for hypothetical future child residents is 1, which is equal to the benchmark of 1.

The risk drivers for cancer risk are arsenic and the combined dioxin and furan congeners. During the 2010 sampling event, arsenic was only detected in one filtered sample (IAA-MW02) at a concentration (1.83 µg/L) that was below the Federal maximum contaminant level (MCL) of 10 µg/L. Arsenic was not detected in any of the filtered samples during the 2008 sampling event. The dioxin and furan congeners that are driving the cancer risks were detected in several groundwater samples during the 2007 sampling event at concentrations greater than the USEPA RSLs. However, most of these constituents were also detected in the rinse blank associated with those samples, which indicated a potential cross contamination issue with the sampling or laboratory equipment. All of the detections during the 2007 sampling event were also below the reporting limit and were qualified as "estimated". During the 2010 sampling event, only one dioxin constituent was detected in a single monitoring well, and the concentration was well below the USEPA RSL, which further indicates dioxin/furan detections from the 2007 sampling event are likely not indicative of groundwater quality at RFAAP-NRU.

Tables A.8.HHRA-8 and A.8.HHRA-9 present the input parameters and the results of the vapor intrusion model for hypothetical future residents. The calculated ELCR was 3×10^{-8}, which is well below the USEPA target risk range of 1×10^{-6} to 1×10^{-4} and the risk estimate for the tapwater ingestion pathway. The hazard index was 3×10^{-6} for both the hypothetical future adult and child resident, which is well below the benchmark of 1.

8.3 NRU Groundwater Summary and Conclusions

An HHRA was conducted to evaluate potential exposure to constituents detected in groundwater. Exposure of hypothetical future residents and site workers to constituents in groundwater assuming the groundwater was used as a potable water supply was evaluated in the risk assessment. Potential exposure of site workers and potential future residents was also evaluated for the vapor migration pathway.

Groundwater

Summary of Calculated ELCRs and HIs for Receptor Exposure Scenarios

RECEPTOR/ EXPOSURE MEDIUM – SCENARIO	ELCR	HI
Site Worker		
Groundwater - Potable Use and Subsurface Vapor Intrusion	4E-05	0.4
Hypothetical Future Adult Resident		
Groundwater - Potable Use and Subsurface Vapor Intrusion		0.6
Hypothetical Future Child Resident		
Groundwater - Potable Use and Subsurface Vapor Intrusion		1
Hypothetical Future Resident (Adult and Child)		
Groundwater - Potable Use and Subsurface Vapor Intrusion	2E-04	

The excess lifetime cancer risks calculated for site worker exposure to groundwater used as a potable water supply was 4×10^{-5}. This is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The hazard index was calculated to be 0.4, which was below the benchmark of 1.

The excess lifetime cancer risks calculated for hypothetical futureresident exposure to groundwater used as a potable water supply was 2×10^{-4}. This is slightly above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The risk drivers for cancer risk are arsenic and the dioxin and furan congeners.

The hazard index for a hypothetical adult resident was calculated to be 0.6, which was below the benchmark of 1. The hazard index or a hypothetical child resident was calculated to be 1, which is equal to the benchmark of 1.

The calculated risks to site workers via the vapor intrusion exposure pathway were well below the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. Exposure of hypothetical future adult and child residents through the vapor intrusion exposure pathway yielded similar, very low results.

The risk drivers for the excess lifetime cancer risk are arsenic and the dioxin and furan congeners. Arsenic was detected in 1 out of the 18 samples collected; however, this detection was below the MCL. The dioxin congeners were detected in three groundwater samples at concentrations greater than the USEPA RSLs. Many of the dioxin compounds were detected in the rinse blank which indicates a potential cross contamination issue associated with the sampling or laboratory equipment. All of the detections were below the reporting limit and were qualified as estimated. Furthermore, the dioxin and furan congeners were not detected in the groundwater samples collected during the 2010 confirmation sampling event which provides futher evidence that the detections driving the elevated risk levels are not indicative of groundwater quality at the facility.

9. NRU Summary and Conclusions

Human health and ecological risk assessments were performed for the areas of the RFAAP-NRU. The purpose of the risk assessments was to evaluate the potential current and future excess lifetime cancer risks and potential hazards to both human and ecological receptors at the site from exposure to constituents detected in soil, groundwater, surface water, and sediment at the RFAAP-NRU.

The primary findings of the assessment are summarized in table below and discussed in the following sections. In particular, discussions regarding the BDDT and the WBG describe the findings where alternative data combinations and receptors were considered. None of the risk estimates for these additional scenarios or receptors were significantly different from the findings of the primary evaluations. That is, no risk-based findings regarding of suitability of any area for a particular use would change under conditions considered in the additional evaluations at the BDDT or WBG.

Summary of Calculated Total ELCRs and HIs for All Constituents Except Lead

Exposure Area	Receptor	ELCR	HI	Risk/Hazard Drivers
BDDT (Entire)	Current Site Worker	7E-05	0.6	-
	Future Construction Worker	2E-06	1	-
	Future Resident	4E-04	0.6 adult, 5 child	Benzo(a)pyrene, Cobalt
BLA	Current Site Worker	1E-04	0.8	-
	Future Construction Worker	7E-06	3	Copper
	Future Resident	1E-03	1 adult, 12 child	Benzo(a)pyrene, Copper, Cobalt, Aroclor 1254
IAA	Current Site Worker	1E-04	1	-
	Future Construction Worker	6E-06	3	*
	Future Resident	5E-04	1 adult, 13 child	2,4-DNT, Aroclor 1254, copper
RY	Current Site Worker	1E-04	0.4	-
	Future Construction Worker	5E-06	0.7	-
	Future Resident	3E-04	0.6adult, 3 child	Pentachlorophenol, cobalt

Summary of Calculated Total ELCRs and HIs for All Constituents Except Lead (continued)

Exposure Area	Receptor	ELCR	HI	Risk/Hazard Drivers
WBG	Current Site Worker	1E-05	0.4	-
	Future Construction Worker	5E-07	0.5	-
	Future Resident	5E-05	0.8 adult, 6 child	Chromium
GW	Site Worker	4E-05	0.4	-
	Future Resident	2E-04	0.6 adult, 1 child	Arsenic, Dioxins/Furans

*When segregated by target organ/critical effect, HI did not exceed 1.

Summary of Estimated Blood Lead Levels

Exposure Area	Receptor	Estimated Blood Lead Level (µg/dL)		
		Adult	Child	Fetus
		50th	Range	95th percentile
BDDT	Not a COPC in this area			
BLA	Current Site Worker	5	–	17
	Future Construction worker	5	–	18
	Future Adult Resident	7	–	23
	Future Child Resident	–	11 - 18	–
IAA	Current Site Worker	3	–	10
	Future Construction	3	–	10
	Future Adult Resident	3	–	11
	Future Child Resident	–	4.4 - 8.2	–
RY	Not a COPC in this area			
WBG	Current Site Worker	2	–	7
	Future Construction	2	–	7
	Future Adult Resident	2	–	7
	Future Child Resident	–	3 - 6	–
GW	Not a COPC in groundwater			

9.1 BDDT

An HHRA was conducted to evaluate exposure to COPCs in surface soil, combined surface and subsurface soil, sediment, and surface water for site workers, construction workers, hypothetical adult residents, and hypothetical child residents under both current and future land-use conditions. Risk findings considering the entire BDDT are summarized above. The results of the HHRA indicate that potential risks associated with the site are within acceptable ranges for current and future industrial use of the site. For hypothetical residential exposures, the calculated excess lifetime cancer risks and hazards were above the USEPA's target risk range of 1 × 10^{-6} to 1 × 10^{-4} or greater than the hazard index of 1. Excess risks were associated with exposure to benzo(a)pyrene in soil. The hazard index was due to the maxium concentration of cobalt in surface soil, the only concentration exceeding the background range. An additional set of calculations evaluating exposure to the rip rap portion alone indicated that risks would be lower there than for the BDDT as a whole. The results of the HHRA indicate that residential redevelopment of the BDDT area as a whole or the rip rap portion alone would not result in risks or hazards outside the regulatory benchmarks, with the exception of residential exposure to benzo(a)pyrene and the maximum concentration of cobalt. Exposure to cobalt resulted in elevated hazards for adult and child residents. All of the other detections of cobalt at the BDDT were within the background range.

A SLERA and BERA were completed for the BDDT, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that adverse effects are not expected for wildlife at the BDDT.

The results of the HHRA and ERA indicated that potential risks associated with the site are within acceptable ranges for current and future industrial use of the site. The risk drivers for a residential use scenario are benzo(a)pyrene and cobalt. Cobalt was only detected in one isolated sample at a concentration above an applicable screening level. The elevated cobalt detection is unlikely the result of disposal activities at the site and is likely naturally occurring.

9.2 BLA

For the purposes of the HHRA, surface soil, total soil, surface water and sediment were evaluated for both current and future land-use conditions. Under current land-use conditions, site worker exposures to surface soil, surface water, and sediment were evaluated. Under future conditions, the site worker exposures remained the same as the current exposures and construction or excavation worker, adult resident and child resident exposures to total soil, surface water, and sediment were evaluated.

The potential cumulative risk for site workers exposed to surface soil and sediment at the BLA under current and future land-use conditions was at the high end of USEPA's target risk range of 1 × 10^{-6} to 1 × 10^{-4} for health protectiveness at Superfund sites

(USEPA, 1990). The potential cumulative HI for site workers was less than the benchmark of 1.

The potential cumulative risk for construction workers were within the USEPA's target risk range of 1×10^{-6} to 1×10^{-4} for health protectiveness at Superfund sites (USEPA, 1990). The potential cumulative HI for construction workers was above the benchmark of 1. When the HI was segregated into target site and critical effects, hazards were above the benchmark of 1 for the gastrointestinal tract due to the presence of copper.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water was greater than the USEPA target risk range of 1×10^{-6} to 1×10^{-4}, due to the presence of benzo(a)pyrene. The total cumulative HI for hypothetical future adult residents was 1, which is equal to the benchmark of 1. The total cumulative HI for hypothetical future child residents is 12, which is greater than the benchmark of 1. When the HI is segregated into target site and critical effects, hazards were above the benchmark of 1 in the central nervous system, whole body, and immune system, in the gastrointestinal tract, and in the eyes, nails, hair, and skin, due to the presence of Aroclor 1254, copper, and cobalt.

Lead was a constituent of potential concern for each of the receptors considered in the BLA risk assessment. Exposure to lead is evaluated differently than the other constituents with the point of comparison based on a predicted blood lead level. For each of the receptors, exposure to lead resulted in predicted elevated blood lead levels. Therefore, exposure to lead could result in an unacceptable risk.

Removal of the walls and roofs of the BLA buildings has exposed conductive flooring material to weather, causing it to degrade and wash onto the surrounding soils. Based on the results of activity-based air sampling conducted in soils surrounding some of those buildings, it appears that the presence of asbestos in soil may present an unaccepble risk for current and future site workers and hypothetical future residents.

A SLERA and BERA were completed for the BLA, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that some of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils and some individual piscivorous mammals and birds exposed to sediment and/or surface water. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, effects of these COPECs at the population-level are unlikely at the BLA.

The results of the HHRA activities indicated that exposure to lead by a site worker could result in adverse health effects. Benzo(a)pyrene, Aroclor 1254, cobalt, and copper were also found to be potential risk drivers under a residential land use scenario. The presence of asbestos in the conductive flooring and surrounding soils may also create risks for future site workers or residents. The ERA activities indicated the potential for risk to individual ecological receptors (i.e., short-tailed shrew and the American robin) due to Hazard Quotients (HQs) greater than 1 for Aroclor 1254, cadmium, copper, lead, and zinc; although no adverse population-level effects would be expected due to the limited areal distribution of these constituents.

9.3 IAA

An HHRA was conducted at the IAA to evaluate potential exposures associated with site constituents to humans. Site worker exposures to surface soil and sediment were evaluated under current and future land-use conditions; and construction worker, adult resident, and child resident exposures to total soil and sediment were evaluated under future land-use conditions.

The soil and sediment COPCs were evaluated for direct contact. VOCs identified as COPCs in the IAA were also evaluated for inhalation via vapor migration into buildings. Two VOCs, 3-octanone and d-limonene, do not have identified inhalation toxicity values; therefore, the indoor vapor intrusion pathway could not be assessed at this Study Area.

A current or future site worker could be present at the IAA area, and could be exposed to surface soil or sediment. The total cumulative ELCR for site workers exposed to surface soil and sediment is at the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is less than the benchmark of 1. Lead was also evaluated as a COPC, although the results are reported differently than those for the other COPCs. The predicted worker blood lead levels were below the benchmark and the predicted fetal lead level was equal to the benchmark.

A hypothetical future construction worker could be present at the IAA area, and could be exposed to combined surface and subsurface soil. The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the IAA was within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is greater than the benchmark of 1. However, when the hazard index was segregated by target organ or critical effect, all of the HIs were below the benchmark of 1. The predicted worker blood lead levels were below the benchmark and the predicted fetal lead level was equal to the benchmark.

The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil and sediment at the IAA is slightly above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The primary risk driver is 2,4-dinitrotoluene in soil. Other contributors to the excess lifetime cancer risks were benzo(a)pyrene and arsenic. The total cumulative HI for hypothetical future adult residents is 1, which is equal to the benchmark of 1. The predicted adult resident blood lead levels were below the benchmark and the predicted fetal lead level was slightly greater than the benchmark. The total cumulative HI for hypothetical future child residents is 13, which is above the benchmark of 1. When the HI was segregated by target site and critical effects, hazards were greater than the benchmark of 1 due to the presence of Aroclor 1254, copper, cobalt, and 2,4-dinitrotoluene. The predicted blood lead levels were all below the benchmark.

Removal of the walls and roofs of the IAA buildings has exposed conductive flooring material to weather, causing it to degrade and wash onto the surrounding soils. Based on the results of activity-based air sampling conducted in soils surrounding some of those buildings, it appears that the presence of asbestos in soil may present an unaccepblerisk for current and future site workers and hypothetical future residents.

A SLERA and BERA were completed for the IAA, to evaluate surface soil and sediment for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that some of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils and some individual piscivorous mammals and birds exposed to sediment and/or surface water. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, population-level effects of these COPECs are unlikely at the IAA.SLERA

The results of the HHRA activities indicated that exposure to 2,4-DNT, Aroclor 1254, copper, cobalt and lead were potential risk drivers under a hypothetical future residential use scenario. The presence of asbestos in the conductive flooring and surrounding soils may also create risks for future site workers or residents. The ERA activities indicated a potential for risk to individual ecological receptors due to HQs greater than 1, although no adverse population-level effects would be expected due to the limited areal distribution of these constituents.

9.4 RY

The HHRA for the RY evaluated current and future land-use conditions for site workers and hypothetical future use for construction workers and adult and child residents. Exposure of these receptors to the soil, sediment, and surface water COPCs was evaluated in the risk assessment. Although exposure to VOCs in soil migrating into buildings was identified as a potential exposure pathway, inhalation toxicity values were not available for the two VOCs, 3-octanone and ethanol, identified as soil COPCs at the RY. Therefore, this exposure pathway was not evaluated quantitatively.

A current or future site worker could be present at the RY area, and could be exposed to surface soil, sediment, or surface water. The total cumulative ELCR for site workers exposed to surface soil, sediment, and surface water at the RY is at the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for site workers is less than the benchmark of 1.

A hypothetical future construction worker could be present at the RY area, and could be exposed to combined surface and subsurface soil. The total cumulative ELCR for hypothetical future construction workers exposed to combined surface and subsurface soil at the RY was within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The total cumulative HI for hypothetical future construction workers is less than the benchmark of 1.

A hypothetical future resident could be present at the RY area, and could be exposed to combined surface and subsurface soil, sediment, or surface water. The total cumulative ELCR for hypothetical future residents exposed to combined surface and subsurface soil, sediment, and surface water at the RY is slightly above the high end of the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. This risk driver for cancer risk is pentachlorophenol which was detected in two samples, one at an estimated value of 0.11 mg/kg and one at a maximum concentration of 830 mg/kg. The one high detection was from a sample collected in April of 1998 and the results were not duplicated in subsequent sampling. The risk assessment was based on the maximum detected concentration and thus may overestimate potential exposures. Without pentachlorophenol as a risk driver, the total cumulative ELCR for the hypothetical future child resident would be within the target risk range.

The total cumulative HI for hypothetical future adult residents is less than the benchmark of 1. The total cumulative HI for hypothetical future child residents is greater than the benchmark of 1. The primary contributor to the non-cancer hazard above 1 is cobalt. The maximum cobalt concentration of 74.9 mg/kg is only slightly greater than the background concentration of 72.3 mg/kg and is well within the range of background levels. Therefore, it is likely that cobalt is present due to naturally occurring sources rather than due to activities at the RY.

The results of the human health risk assessment indicate that use of the RY for residential or industrial uses should not result in unacceptable risks to potential receptors.

A SLERA and BERA were completed for the RY, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial and aquatic food chain models indicate that a few of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils and some individual piscivorous mammals and birds exposed to sediment and/or surface water, if all exposure assumptions are met. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, adverse affects at the population-level are considered unlikely for the shrew (or other insectivorous mammals) and the robin (or other insectivorous birds) exposed to the constituents at the RY.

9.5 WBG

The HHRA evaluated potential current exposure of site workers to surface soil, surface water, and sediment, potential future exposures of construction workers to total soil and potential future adult and child resident exposure to total soil, surface water, sediment, and fish caught in the pond at the WBG. The soil, sediment, and surface water COPCs were evaluated for direct contact. In addition, a scenario was evaluated that specifidally considered exposure to sediment during participation in the semi-annual fishing rodeo, and risks to all potential future receptors were evaluated in the event that the pond were drained and current sediments became eligible for direct contact in the same frequency, intensity, and duration as soils.

VOCs identified as COPCs in the WBG were also evaluated for inhalation via vapor migration into buildings. One VOC, d-limonene, was identified as a soil COPC at the

WBG, but since it does not have identified inhalation toxicity value, this exposure pathway was not evaluated quantitatively. Potential risks and hazards for site workers and construction workers, including exposure to lead, under current industrial land use conditions were within generally acceptable levels and benchmarks. Under a hypothetical future residential land use, potential hazards associated with chromium in sediment were slightly greater than the benchmark of 1 for the child resident. Potential risks associated with exposure to lead in soil and sediment could result in adverse health effects. The elevated blood lead levels were driven by the concentration of lead in the sediments. No other scenarios evaluated resulted in an unacceptable risk level. The risk findings are applicable to both current land use conditions and those that would result if the pond were drained and current sediments became part of the soil eligible for direct contact exposures.

Based on the results of the risk assessment, it is unlikely that industrial use of the property would result in adverse health effects. For the residential exposure scenarios, exposure to lead in sediments may pose an adverse health effect if the exposure assumptions are different than actual exposures. Also, exposure to chromium in sediments may pose a slightly elevated hazard to children wading in surface water. Several (four) of the detections fell outside of the background chromium soil range. The maximum chromium sediment concentration of 15,400 mg/kg is well above the background range.

A SLERA and BERA were completed for the WBG, to evaluate surface soil, sediment, and surface water for ecological receptors, and food chain modeling was evaluated for all those constituents identified as bioaccumulative. The results of the evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the terrestrial food chain model indicate that some of the NOAEL and LOAEL HQs were greater than 1, which suggests the potential for risk to some individual insectivorous mammals and birds exposed to surface soils and some individual piscivorous mammals and birds exposed to sediment and/or surface water. However, when these results are considered in conjunction with pertinent site information on the limited spatial distribution and extent of these constituents, adverse affects of these COPECs at the population-level are unlikely at the WBG.

Similarly, the results of the sediment and surface water evaluation of the SLERA and BERA for direct contact and the constituents evaluated in the aquatic food chain model indicate that adverse population-level effects are not expected for aquatic life exposed to bioaccumulative COPECs in sediment and/or surface water at the WBG.

9.6 Groundwater

An HHRA was conducted to evaluate potential exposure to constituents detected in groundwater. Exposure of hypothetical future residents and site workers to constituents in groundwater assuming the groundwater was used as a potable water supply was evaluated in the risk assessment. Potential exposure of site workers and potential future residents was also evaluated for the vapor migration pathway. The excess lifetime cancer risks calculated for site worker exposure to groundwater used as a potable water supply was 4×10^{-5}. This is within the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The hazard index was calculated to be 0.4, which was below the benchmark of 1.

The excess lifetime cancer risks calculated for hypothetical futureresident exposure to groundwater used as a potable water supply was 2×10^{-4}. This is slightly above the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. The risk drivers for cancer risk are arsenic and the dioxin and furan congeners.

The hazard index for a hypothetical adult resident was calculated to be 0.6, which was below the benchmark of 1. The hazard index or a hypothetical child resident was calculated to be 1, which is equal to the benchmark of 1.

The calculated risks to site workers via the vapor intrusion exposure pathway were well below the USEPA target risk range of 1×10^{-6} to 1×10^{-4}. Exposure of hypothetical future adult and child residents through the vapor intrusion exposure pathway yielded similar, very low results.

The risk drivers for the excess lifetime cancer risk were arsenic and the dioxin congeners. Arsenic was detected in 1 out of the 18 samples collected; however, this detection was below the MCL. The dioxin congeners were detected in three groundwater samples at concentrations greater than the USEPA RSLs. Many of the dioxin compounds were detected in the rinse blank which indicates a potential cross contamination issue associated with the sampling or laboratory equipment. All of the detections were below the reporting limit and were qualified as estimated. Furthermore, dioxins were not detected in groundwater samples collected during the 2010 sampling event which provides additional evidence that the previous dioxin detections were not indicative of actual groundwater quality at the facility.

Notes:
COPC = Constituent of Potential Concern
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Regional screening levels were from USEPA (2009a).

The screening levels used were risk screening levels for the residential scenario from USEPA (2009a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n SL < 100X c SL; ** = where n SL < 10X c SL; n = noncancer; m = Concentration may exceed ceiling limit;
s = Concentration may exceed saturation concentration (Csat).
< The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.

[b] Adjusted soil screening levels were used to assess soil and sediment at the NRU.
[c] Adjusted tap-water screening levels were used to assess surface water and groundwater at the NRU.

Table A.2-2
Metals Background Levels
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Constituent	Range of Detects (mg/kg)		95% UTL
	Min	Max	
Aluminum	3620	47900	40041

(1) Dermal absorption efficiency for uptake of constituents from a soil matrix (unitless) (USEPA 2004c).
(2) Permeability coefficient for dermal contact with constituents in water (centimeters per hour).
(3) Absorption parameters for use in the non-steady state model for dermal contact with constituents in water.
τ = Lag time for dermal absorption through the skin.
B = Ratio of the permeability coefficient through the stratus corneum relative to the permeability coefficient across the viable epidermis.
FA = Fraction of absorbed water.
t* = Time required to reach steady state.
(4) Dermal absorption (DA) calculated according to equations presented on Tables 5-11 and 5-12 and based on exposure time (ET) = 1 hour.

References:
calc = Calculated value (USEPA 2004c).
DRA = USEPA (2004c) (Dermal Risk Assessment). The B values are calculated but are consistent with values presented in USEPA (2004c) guidance.
EPI = EPI Suite (USEPA 2000).
RAIS = Risk Assessment Information System (USDOE 2008).
W = Assumed to be equal to the value for water (USEPA 2004c).

cm = Centimeter.
L = Liter.
USEPA = United States Environmental Protection Agency.

[a] The averaging time for cancer risk is the expected lifespan of 70 years expressed in days.
The averaging time for non-cancer hazard is the total exposure duration expressed in days.
[b] EFwade was set at 48 days/year for the resident receptor assuming twice a week during the six warm months of the year.
EFwade was set at 26 days per year for the worker receptor assuming exposure once every two weeks.
[c] SSAs assumes that a receptor is wearing a short-sleeved shirt, shorts, and shoes therefore the
SSAs is the average surface area for the head, hands, forearms, and lower legs.
[d] SSAsed and SSsw assumes that a receptor is wearing a short-sleeved shirt and shorts but not shoes therefore the
SSAed and SSAsw is the average surface area of feet, hands, forearms, and lower legs.
[e] SSAs assumes that a receptor is wearing a short-sleeved shirt, long-pants, and shoes therefore the
SSAs is the average surface area of hands, forearms, and face (average for men and women).
[f] SSAsed and SSsw assumes that a receptor is wearing a short-sleeved shirt and shorts but not shoes therefore the
SSAed and SSAsw is the average surface area of feet, hands, forearms, and lower legs.

cm	Centimeter.	m	Meter.	PJ	Professional judgment (see text).
kg	Kilogram.	mg	Milligram.	yr	Year.
L	Liter.				

Table A.2-11
Risk and Hazard Equations for Exposure to Soil
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

ROUTE-SPECIFIC RISK/HAZARD:

Oral:

$$ELCR_o \text{ or } HQ_o = \frac{EPCs \times FI \times IRs \times EF \times ED}{(10^6 \text{ mg/kg}) \times BW \times (AT_C \text{ or } AT_{NC}) \times ([1/CSF_o] \text{ or } RfD_o)}$$

Dermal:

$$ELCR_d \text{ or } HQ_d = \frac{EPCs \times SSAs \times SAR \times ABSd \times EF \times ED}{(10^6 \text{ mg/kg}) \times BW \times (AT_C \text{ or } AT_{NC}) \times ([1/CSF_a] \text{ or } RfD_a)}$$

Inhalation:

$$ELCR_i \text{ or } HQ_i = \frac{EPC_i \times BRs \times EF \times ED}{(VF \text{ or } PEF) \times BW \times (AT_C \text{ or } AT_{NC}) \times ([1/CSF_i] \text{ or } RfD_i)}$$

$$VF = \frac{Q/C_{vol} \times [3.14 \times D_A \times T]^{1/2}}{2 \times \rho_b \times D_A \times (10{,}000 \text{ cm}^2/\text{m}^2)}$$

used for VOCs

$$PEF = \frac{Q/C_{wind} \times (3{,}600 \text{ sec/hr})}{RPF \times (1-V) \times (Um/Ut)^3 \times Fx}$$

used for non-VOCs

$$D_A = \frac{[(\theta_{as}^{10/3} \times D_{air} \times H_o) + (\theta_{ws}^{10/3} \times D_{wat})] / \theta_T^2}{(\rho_b \times Koc \times Foc) + \theta_{ws} + (\theta_{as} \times H_o)}$$

EPC_i = MINIMUM [EPCs, C_{sat}] OR = EPCs when C_{sat} is not relevant

$$C_{sat} = \frac{S}{\rho_b} \times [(Koc \times Foc \times \rho_b) + \theta_{ws} + (H_o \times \theta_{as})]$$

C_{sat} is relevant only for organic constituents with melting point below 30ºC.

For potentially mutagenic carcinogens (i.e.,PAHs), the ED and ATc of any ELCR equation are removed; 365 days/year replaces ATc; and the equation is adjusted by (4.6*(2/70))+(2.1*(4/70)) for child resident receptors and (2.1*(10/70))+(1*(14/70)) for adult resident receptors.

TOTAL CANCER RISK: $ELCR = ELCR_o + ELCR_d + ELCR_i$

TOTAL NON-CANCER HAZARD: $HI = HQ_o + HQ_d + HQ_i$

Variable Definitions:

θ_{as}	Air-filled porosity of the soil (unitless).
θ_T	Total soil porosity (unitless).
θ_{ws}	Water-filled porosity of the soil (unitless).
ρ_b	Dry soil bulk density (g/cm³).
ABSd	Dermal absorption efficiency (unitless) (Table A.2-8).
AT_C	Averaging time for cancer effects (days) (Table A.2-10).
AT_{NC}	Averaging time for noncancer effects (days) (Table A.2-10).
BRs	Breathing rate for soil exposure (m³/day) (Table A.2-10).
BW	Body weight (kg) (Table A.2-10).
C_{sat}	Constituent saturation limit in soil (mg/kg).
CSF	Cancer slope factor for oral (CSF_o), dermal (adjusted to an absorbed dose, CSF_a), or inhalation (CSF_i) exposure (kg-day/mg [inverse mg/kg/day]) (Tables A.2-6 and A.2-7).
D_A	Apparent diffusivity in soil (cm²/sec).
D_{air}	Constituent diffusivity in air (cm²/sec) (Table A.2-3).
D_{wat}	Constituent diffusivity in water (cm²/sec) (Table A.2-3).
ED	Exposure duration (years) (Table A.2-10).
EF	Exposure frequency (days/year) (Table A.2-10).

Table A.2-11
Risk and Hazard Equations for Exposure to Soil
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

ELCR	Excess lifetime cancer risk (unitless).
EPCs	Exposure point concentration in soil (mg/kg).
EPC_i	Exposure point concentration relevant to inhalation (mg/kg) (minimum of EPCs and C_{sat}).
FI	Fraction ingested from area of concern (unitless) (Table A.2-10).
Foc	Fraction organic carbon in the soil (unitless).
Fx	Function of Ut/Um (unitless); $Fx = 0.18 \times (8x^3 + 12x) \times \exp[-(x^2)]$, where $x = 0.886 \times (Ut/Um)$.
H	Henry's law constant ($atm\text{-}m^3/mol$) (Table A.2-3).
HI	Hazard index for non-cancer effects (unitless); sum of the HQs.
H_o	Dimensionless Henry's law constant (unitless); calculated as $H_o = H / RT$.
HQ	Hazard quotient for non-cancer effects (unitless).
IRs	Ingestion rate of soil (mg/day) (Table A.2-10).
Koc	Organic carbon partition coefficient ($cm^3/g = mL/g = L/kg$) (Table A.2-3).
PEF	Particulate emission factor (m^3/kg).
Q/C_{vol}	Volatile emission flux per unit concentration $[(g/m^2/sec)/(kg/m^3)]$.
Q/C_{wind}	Particulate emission flux per unit concentration $[(g/m^2/sec)/(kg/m^3)]$.
RfD	Reference dose for oral (RfD_o), dermal (adjusted to an absorbed dose, RfD_a), or inhalation (RfD_i) exposure (mg/kg/day) (Tables A.2-4 and A.2-5).
RPF	Respirable particle fraction (0.036 $g/m^2/hr$).
RT	Product of the universal gas constant ($R = 8.206 \times 10^{-5}$ $atm\text{-}m^3/mol/K$) and the relevant Kelvin temperature (T = 298.15 K); RT = 0.02447 $atm\text{-}m^3/mol$.
S	Constituent solubility limit in water (mg/L).
SAR	Soil-to-skin adherence rate ($mg/cm^2/day$) (Table A.2-10).
SSAs	Exposed skin surface area for soil contact (cm^2) (Table A.2-10).
T	Exposure interval (sec).
Um	Mean annual wind speed (m/sec).
Ut	Equivalent threshold value of windspeed at 7 meters (11.32 m/sec).
V	Fraction of vegetative cover (unitless).
VF	Volatilization factor (m^3/kg).
x	Intermediate value in the calculation of PEF; $x = 0.886 \times (Ut/Um)$.

VOCs Volatile organic compounds.

Table A.2-12
Risk and Hazard Equations for Exposure to Sediment
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

ROUTE-SPECIFIC RISK/HAZARD:

Oral:

$$ELCR_o \text{ or } HQ_o = \frac{EPCsed \times IRsed \times EF \times ED}{(10^6 \text{ mg/kg}) \times BW \times (AT_C \text{ or } AT_{NC}) \times ([1/CSF_o] \text{ or } RfD_o)}$$

Dermal:

$$ELCR_d \text{ or } HQ_d = \frac{EPCsed \times SSAsed \times SedAR \times ABSd \times EF \times ED}{(10^6 \text{ mg/kg}) \times BW \times (AT_C \text{ or } AT_{NC}) \times ([1/CSF_a] \text{ or } RfD_a)}$$

For potentially mutagenic carcinogens (i.e.,PAHs), the ED and ATc of any ELCR equation are removed; 365 days/year replaces ATc; and the equation is adjusted by (4.6*(2/70))+(2.1*(4/70)) for child resident receptors and (2.1*(10/70))+(1*(14/70)) for adult resident receptors.

TOTAL CANCER RISK: $ELCR = ELCR_o + ELCR_d$

TOTAL NON-CANCER HAZARD: $HI = HQ_o + HQ_d$

Variable Definitions:

ABSd	Dermal absorption efficiency (unitless) (Table A.2-8).
AT_C	Averaging time for cancer effects (days) (Table A.2-10).
AT_{NC}	Averaging time for non-cancer effects (days) (Table A.2-10).
BW	Body weight (kg) (Table A.2-10).
CSF	Cancer slope factor for oral (CSF_o) or dermal (adjusted to an absorbed dose, CSF_a) exposure (kg-day/mg [inverse mg/kg/day]) (Table A.2-6).
ED	Exposure duration (years) (Table A.2-10).
EF	Exposure frequency (days/year) (Table A.2-10).
ELCR	Excess lifetime cancer risk (unitless).
EPCsed	Exposure point concentration in sediment (mg/kg).
HI	Hazard index for non-cancer effects (unitless); sum of the HQs.
HQ	Hazard quotient for non-cancer effects (unitless).
IRsed	Ingestion rate of sediment (mg/day) (Table A.2-10).
RfD	Reference dose for oral (RfD_o) or dermal (adjusted to an absorbed dose, RfD_a) exposure (mg/kg/day) (Table A.2-4).
SedAR	Sediment-to-skin adherence rate (mg/cm²/day) (Table A.2-10).
SSAsed	Exposed skin surface area for sediment contact (cm²) (Table A.2-10).

Table A.2-13
Risk and Hazard Equations for Wading Exposure to Surface Water
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

ROUTE-SPECIFIC RISK/HAZARD:

Oral:

$$ELCR_o \ \textit{or}\ HQ_o = \frac{EPCsw \times IRsw \times ETsw \times EF \times ED}{BW \times (AT_C \ \textit{or}\ AT_{NC}) \times ([1/CSF_o] \ \textit{or}\ RfD_o)}$$

Dermal:

$$ELCR_d \ \textit{or}\ HQ_d = \frac{EPCsw \times DA \times SSAsw \times EF \times ED}{BW \times (AT_C \ \textit{or}\ AT_{NC}) \times ([1/CSF_a] \ \textit{or}\ RfD_a)}$$

Inorganics:

$$DA\,[0] = \frac{K_p \times ETsw}{1000\ cm^3/L}$$

Organics:

$$DA\,[1] = \frac{2\,FA \times K_p}{1000\ cm^3/L} \times \sqrt{(6\,\tau \times ETsw)/\pi} \qquad \text{if } ETsw \le t^*$$

or

$$DA\,[2] = \frac{FA \times K_p}{1000\ cm^3/L} \times \left(\frac{ETsw}{1+B} + \frac{2\,\tau\,(1 + 3B + 3B^2)}{(1+B)^2} \right) \qquad \text{if } ETsw > t^*$$

Inhalation:

$$ELCR_i \ \textit{or}\ HQ_i = \frac{EPCsw \times VFsw \times BRsw \times EF \times ED}{BW \times (AT_C \ \textit{or}\ AT_{NC}) \times ([1/CSF_i] \ \textit{or}\ RfD_i)}$$

where:

$$VFsw = \frac{(1000\ L/m^3)}{(1/k_l) + [1/(H_o \times k_g)]} \times \frac{SA}{Hb \times Wb \times Um}$$

TOTAL CANCER RISK: $ELCR = ELCR_o + ELCR_d + ELCR_i$

TOTAL NON-CANCER HAZARD: $HI = HQ_o + HQ_d + HQ_i$

Variable Definitions:

τ	(tau) Lag time for dermal absorption through the skin (hour) (Table A.2-8).
AT_C	Averaging time for cancer effects (days) (Table A.2-10).
AT_{NC}	Averaging time for non-cancer effects (days) (Table A.2-10).
B	Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (unitless) (Table A.2-8).
BRsw	Breathing rate for surface water exposure (m^3/day) (Table A.2-10).
BW	Body weight (kg) (Table A.2-10).
CSF	Cancer slope factor for oral (CSF_o), dermal (adjusted to an absorbed dose, CSF_a), or inhalation (CSF_i) exposure (kg-day/mg [inverse mg/kg/day]) (Tables A.2-6 and A.2-7).
DA	Dermal absorption factor (L/cm^2/day), calculated using Equation [0], [1], or [2], as appropriate.
ED	Exposure duration (years) (Table A.2-10).
EF	Exposure frequency (days/year) (Table A.2-10).
ELCR	Excess lifetime cancer risk (unitless).
EPCsw	Exposure point concentration in surface water (mg/L).
ETsw	Exposure time for surface water (hours/day) (Table A.2-10).
FA	Fraction of absorbed water (unitless) (Table A.2-8).
H	Henry's law constant (atm-m^3/mol) (Table A.2-3).
Hb	Height of mixing zone (2 m).
HI	Hazard index for non-cancer effects (unitless); sum of the HQs.

Table A.2-13
Risk and Hazard Equations for Wading Exposure to Surface Water
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

H_o	Dimensionless Henry's law constant (unitless); calculated as H_o = H/RT.
HQ	Hazard quotient for non-cancer effects (unitless).
IRsw	Incidental ingestion rate of surface water (L/day) (Table A.2-10).
k_g	Gas-phase mass transfer coefficient (m/sec) ≈ (8.3 × 10^{-3} m/sec) × [(18 g/mol)/MW]$^{1/2}$.
k_l	Liquid-phase mass transfer coefficient (m/sec) ≈ (5.6 × 10^{-5} m/sec) × [(44 g/mol)/MW]$^{1/2}$.
K_p	Permeability coefficient (cm/hour) (Table A.2-8).
MW	Molecular weight (g/mol) (Table A.2-3).
RfD	Reference dose for oral (RfD_o), dermal (adjusted to an absorbed dose, RfD_a), or inhalation (RfD_i) exposure (mg/kg/day) (Tables A.2-4 and A.2-5).
RT	Product of the universal gas constant (R = 8.206 × 10^{-5} atm-m^3/mol/K) and the relevant Kelvin temperature (T = 298.15 K); RT = 0.02447 atm-m^3/mol.
SA	Source area (1 m^2).
SSAgw	Exposed skin surface area for surface water contact (cm^2) (Table A.2-10).
t*	Time required to reach steady state (hour) (Table A.2-8).
Um	Mean wind speed (m/sec).
VFsw	Volatilization factor from surface water (L/m^3).
Wb	Width of mixing zone (1 m).

Table A.2-14
Risk and Hazard Equations for Exposure to Surface Water by Fish Ingestion
New River Unit, Radford Army Ammunition Plant, Radford, Virginia.

CANCER RISK:

$$ELCR = \frac{EPCsw \times BCF \times IRfish \times EF \times ED \times CSF_o}{BW \times AT_C}$$

NON-CANCER HAZARD:

$$HQ = \frac{EPCsw \times BCF \times IRfish \times EF \times ED}{BW \times AT_{NC} \times RfD_o}$$

Variable Definitions:	
AT_C	Averaging time for cancer effects (days) (Table A.2-10).
AT_{NC}	Averaging time for non-cancer effects (days) (Table A.2-10).
BCF	Fish bioconcentration factor (L/kg) (Table A.2-3).
BW	Body weight (kg) (Table A.2-10).
CSF_o	Cancer slope factor for oral exposure (kg-day/mg [inverse mg/kg/day]) (Table A.2-6).
ED	Exposure duration (years) (Table A.2-10).
EF	Exposure frequency (days/year) (Table A.2-10).
ELCR	Excess lifetime cancer risk (unitless).
EPCsw	Exposure point concentration in surface water (mg/L).
HQ	Hazard quotient for non-cancer hazard (unitless).
IRfish	Ingestion rate of fish (kg/day) (Table A.2-10).
RfD_o	Reference dose for oral exposure (mg/kg/day) (Table A.2-4).

Table A.2-15
Risk and Hazard Equations for Residential and Industrial Exposure to Groundwater
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

ROUTE-SPECIFIC RISK/HAZARD:

Oral:

$$ELCR_o \text{ or } HQ_o = \frac{EPCgw \times IRgw \times EF \times ED}{BW \times (AT_C \text{ or } AT_{NC}) \times ([1/CSF_o] \text{ or } RfD_o)}$$

Dermal:

$$ELCR_d \text{ or } HQ_d = \frac{EPCgw \times DA \times SSAgw \times EF \times ED}{BW \times (AT_C \text{ or } AT_{NC}) \times ([1/CSF_a] \text{ or } RfD_a)}$$

Inorganics:

$$DA\,[0] = \frac{K_p \times ETgw}{1000\ cm^3/L}$$

Organics:

$$DA\,[1] = \frac{2\,FA \times K_p}{1000\ cm^3/L} \times \sqrt{(6\,\tau \times ETgw)/\pi} \qquad \text{if } ETgw \le t^*$$

or

$$DA\,[2] = \frac{FA \times K_p}{1000\ cm^3/L} \times \left(\frac{ETgw}{1+B} + \frac{2\,\tau\,(1 + 3B + 3B^2)}{(1+B)^2} \right) \qquad \text{if } ETgw > t^*$$

Inhalation:

$$ELCR_i \text{ or } HQ_i = \frac{EPCgw \times VFres \times BRgw \times EF \times ED}{BW \times (AT_C \text{ or } AT_{NC}) \times ([1/CSF_i] \text{ or } RfD_i)}$$

** Note: Inhalation pathway only complete for residential exposure to groundwater while showering **

TOTAL CANCER RISK: $ELCR = ELCR_o + ELCR_d + ELCR_i$

TOTAL NON-CANCER HAZARD: $HI = HQ_o + HQ_d + HQ_i$

Variable Definitions:

τ	Lag time for dermal absorption through the skin (hour) (Table A.2-8).
AT_C	Averaging time for cancer effects (days) (Table A.2-10).
AT_{NC}	Averaging time for non-cancer effects (days) (Table A.2-10).
B	Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (unitless) (Table A.2-8).
BRgw	Breathing rate for groundwater exposure (m^3/day) (Table A.2-10).
BW	Body weight (kg) (Table A.2-10).
CSF	Cancer slope factor for oral (CSF_o), dermal (adjusted to an absorbed dose, CSF_a), or inhalation (CSF_i) exposure (kg-day/mg [inverse mg/kg/day]) (Tables A.2-6 and A.2-7).
DA	Dermal absorption factor (L/cm^2/day), calculated using Equation [0], [1], or [2], as appropriate.
ED	Exposure duration (years) (Table A.2-10).
EF	Exposure frequency (days/year) (Table A.2-10).
ELCR	Excess lifetime cancer risk (unitless).
EPCgw	Exposure point concentration in groundwater (mg/L).
ETgw	Exposure time for groundwater contact (hours/day) (Table A.2-10).
FA	Fraction of absorbed water (unitless) (Table A.2-8).
HI	Hazard index for non-cancer effects (unitless); sum of the HQs.
HQ	Hazard quotient for non-cancer effects (unitless).
IRgw	Ingestion rate of groundwater (L/day) (Table A.2-10).
Kp	Permeability coefficient (cm/hour) (Table A.2-8).
RfD	Reference dose for oral (RfD_o), dermal (adjusted to an absorbed dose, RfD_a), or inhalation (RfD_i) exposure (mg/kg/day) (Tables A.2-4 and A.2-5).

Table A.2-15
Risk and Hazard Equations for Residential and Industrial Exposure to Groundwater
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

SSAgw	Exposed skin surface area for groundwater contact (cm^2) (Table A.2-10).
t*	Time required to reach steady state (hour) (Table A.2-8).
VFres	Residential volatilization factor for household tap water (0.5 L/m^3); applicable only for volatile organic compounds (VOCs) (USEPA 1991).

Table A.2-16
Threatened and Endangered Species Potentially Occurring at the Site
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Scientific Name Common Name	State Rank [a]	State Status [b]	Federal Status [c]	Habitat	Habitat Present at NRU SWMUs
Upland Forest					
Plants:					
Blephilia hirsuta Hairy woodmint	R	WL	NA	Mesic successional woodlands, sinkholes, and ravines.	NO
Panax quinquifolium American ginseng	C	WL	NA	Rich deciduous forests.	NO
Limestone Barren					
Plants:					
Carex meadii Mead's sedge	R	WL	NA	Dry or seasonally moist basic soils.	NO
Linum sulcatum Grooved yellow flax	R	WL	NA	Glades, prairies, and sometimes in open woods.	NO
Calcareous Fen					
Plants:					
Carex interior Inland sedge	ER	RL	NA	Calcaerous Fen natural communities, along small streams or brooks.	NO
Carex schweinitzii Schweinitz's sedge	ER	RL	NA	Strongly calcareous, perennially wet, seepy habitats often in association with rich fens.	NO
Carex suberecta Prairie straw sedge	R	WL	NA	Moist, low-lying areas, fens and other alkaline wetlands.	YES
Carex tetanica Rigid sedge	R	WL	NA	Open or shrubby calcareous wetlands.	YES
Juncus brachycephalus Small-headed rush	VR	RL	NA	Perennial wet ground with a fresh supply of highly alkaline water.	YES
Grassland					
Plants:					
Carex mesochorea Midland sedge	C	WL	NA	Grassland areas.	YES
Onosmodium hispidissimum Shaggy False Gromwell	C	WL	NA	Dry, open, grassy limestone hills, espeically in the vicinity of the bedrock outcrops.	NO
Invertebrates:					
Speyeria idalia Regal Fritillary	ER	ST	NA	Tall-grass prairies, damp meadows, marshes, wet fields, and mountain pastures.	NO
Birds:					
Ammodramus henslowii Henslow's Sparrow	ER	ST	NA	Wet shrubby fields, marshes and open pine woods.	YES
Lanius ludovicianus Loggerhead Shrike	VR	ST	NA	Pastures, savannah, and open brushland.	YES

Footnotes appear on last page.

Table A.2-17

Uncertainties in the Screening-Level and Baseline-Level Ecological Risk Assessments

New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Assumptions	Description And Discussion Related To Uncertainties in ERA	Uncertainty in SLERA	Uncertainty in BERA
Analytical Sampling and Data Analysis			
Limited number of samples	Frequently, there are only a limited number of samples used in ERAs, and very often they are collected in a biased manner (i.e., targeting “hot spots”). This type of sampling often lacks statistical power and does not likely represent the concentrations in the environment in which wildlife exposure occurs. Similarly, limited data used to estimate uptake into organisms may overestimate exposure via the food web.	Overestimate of exposure and risk	Overestimate of exposure and risk
Use of maximum concentrations	Maximum concentrations are used to represent the upper estimate exposures. This practice compensates for uncertainty contributed by limited numbers of samples, but overestimates exposure and risk.	Overestimate of exposure and risk	Overestimate of exposure and risk
Detection limits	Detection limits may exceed ESVs (e.g., PAHs) or thresholds for adverse impacts are well below the analytical methods used in ERA (e.g., compounds that are known or suspected to cause endocrine effects).	May underestimate risk or effect on risk estimate unknown	May underestimate risk or effect on risk unknown
Degradation of chemicals not considered	ERAs are almost exclusively based on concentrations of target compounds, and little if any attention is given to degradation compounds that could be more toxic than the original chemical. Conversely, chemical concentrations may decrease over time due to natural physical processes.	Effect on risk estimate unknown	Effect on risk estimate unknown
Selection of COPCs			
Background concentrations	Chemicals may be identified as COPCs despite the fact that the detected concentrations are less than background concentrations. For the purpose of this assessment, screening against soil background was conducted as part of the initial COPEC screen. However, background data for sediment and surface water were not available, therefore, no consideration of background was given for those media.	Overestimate of risk for aquatic receptors	Not Applicable
Toxicology and ESVs			
Toxicity and exposure data for a limited number of species	Uncertainties exist in many aspects of the toxicology relied upon for conducting ERAs (Newman 1998; Lovett Doust et al. 1993). Toxicity and wildlife exposure data are only available for a limited number of species (most of them laboratory test species) under a strictly defined set of test conditions that deviate from natural conditions (Sample et al. 1996; Suter 1996a; Sample et al. 1997)	Effect on risk estimate unknown	Effect on risk estimate unknown
Laboratory testing	In current practice, more than 95 percent of the resources in toxicology are focused toward the study of single chemicals (Cassee et al. 1998), while wildlife exposures rarely occur on a chemical-specific basis. Simplistic extrapolations from laboratory species to wildlife species and testing conditions to field conditions are not likely accurate, and are rarely, if ever, validated against natural conditions (Power 1996; Tannenbaum 2003).	Effect on risk estimate unknown	Effect on risk estimate unknown
Adaptation and tolerance	There is little consistency and no quantitative methodology for the consideration of the diminished bioavailability (and, thereby, diminished toxicity) even though this process is well documented (e.g., Alexander and Alexander 1999; Alexander 2000). Similarly, tolerance and adaptation are not considered directly (Millward and Klerks 2002; Grant 2002). Furthermore, the white rat often used in toxicological testing is bred to minimize differences between lab animals, thereby diminishing the genetic variability that gives wildlife some capability for adaptation and tolerance (Tannenbaum 2003).	Overestimate of risk	Overestimate of risk
Predator-prey interactions	There are relatively few studies that actually evaluate the effects of toxicity on predator-prey interactions, or on competition for scarce resources (Atchison et al. 1996), the very conditions within which all wildlife exists (Kapustka and Landis 1998).	Effect on risk estimate unknown	Effect on risk estimate unknown

Table A.2-17
Uncertainties in the Screening-Level and Baseline-Level Ecological Risk Assessments
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Assumptions	Description And Discussion Related To Uncertainties in ERA	Uncertainty in SLERA	Uncertainty in BERA
HQs			
HQs based on maximum	The SLERA HQ is based on the maximum detected concentrations and the most conservative ESVs available (USEPA 1997c; 2000b). HQs in the BERA are based on the exposure point concentration (minimum of the 95% upper confidence limit on the mean and the maximum concentration).	Overestimate of risk	Overestimate of risk
Elevated HQs for background concentrations	HQs may exceed a value of 1 for background concentrations of naturally occurring metals (Tannenbaum 2003). This is due to many of the toxicology and ESV uncertainties already discussed.	Overestimate of risk	Overestimate of risk
Interpretation of HQs	An HQ less than or equal to a value of 1 indicates that adverse impacts to wildlife are considered unlikely (USEPA 2001c). However, there is no clear guidance for interpreting the HQs that exceed a value of 1, except that this point of departure indicates that adverse effects of some kind may have occurred or may occur in the future.	Effect on risk estimate unknown	Effect on risk estimate unknown
HQs for individual used to evaluate risks to populations	HQs are based on the types of impacts that could occur to individuals (i.e., those individuals exposed to maximum concentrations) and they completely fail to address ecological exposure and risk at spatial scale of populations (Tannenbaum 2003; Durda and Preziosi 1999).	Overestimate of risk to wildlife populations	Overestimate of risk to wildlife populations
HQs with unrealistic	HQs are seen at magnitudes that suggest that every animal should die upon acute exposure (i.e., in the hundreds or thousands) (Tannenbaum et al. 2003). Often, physical conditions at a site demonstrate that this is not the case.	Overestimate of risk	Overestimate of risk
No evaluation of dermal or inhalation pathways	The dermal and inhalation exposure pathways are generally considered “insignificant” due to protective fur and feathers. Under certain conditions, these exposure pathways may occur, but adequate information is rarely available by which to evaluate them.	Not Applicable	Potentially an underestimate of risk

BERA	Baseline Ecological Risk Assessment.
COPC	Constituent of potential concern.
ERA	Ecological risk assessment.
ESV	Ecological screening value.
HQ	Hazard quotient.
PAH	Polynuclear aromatic hydrocarbon.
RTV	Reference toxicity value.
SLERA	Screening level ecological risk assessment.

Notes:
– = Not available or applicable.
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.
NA = Not available or applicable.
s = surrogate was used.

[a] Toxicity Equivalency Factor (TEF); Federal Register Vol. 72, No. 90 (USEPA 2007d).
[b] Surrogates were used were screening values were not available.
[c] Ecological soil screening levels were from the following sources in order of priority:
Region 5 Ecological Screening Levels (USEPA 2003a; R5).
Oak Ridge National Laboratory (Efroymson et. Al. 1997a,b; ORNL).
Nitroaromatic Munition Compounds: Environmental Effects and Screening Values (Talmage et al. 1999; T).
For EcoSSL and ORNL SLs, the lowest value for all available endpoints was selected.
[d] Ecological sediment screening levels were from the following sources in order of priority:
USEPA Ecological Soil Screening Levels (USEPA 2005b; EcoSSL).
Region 3 Sediment Screening Levels (USEPA 2008a, R3).
Oak Ridge National Laboratory (Suter et al. 1997; ORNL); the lowest value for all available endpoints was selected.
Region 5 Sediment Screening Levels (USEPA 2003e; R5).
Sediment screening level for aluminum was from USEPA Assessment and Remediation of Contaminated Sediments Program (ARCS), obtained from Jones et. al. 1997.
[e] Ecological surface water screening levels were from the following sources in order of priority:
Region 3 Fresh Water Screening Levels (USEPA 2008b; R3).
Oak Ridge National Laboratory (Suter et al. 1997; ORNL); the lowest value for all available endpoints was selected.
Region 5 Surafce Water Screening Levels (USEPA 2003e; R5).
USEPA National Ambient Water Quality Criteria (USEPA 2008c).
[f] The following sources were consulted to identify bioaccumulation potential: USEPA Region 3 (USEPA 2008a,b); USEPA (2000c).

Table A.2-20
Bioconcentration and Bioaccumulation Factors for Soil
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

– =	Not applicable.
BAF =	Bioaccumulation Factor (unitless); BAF = (Tissue Concentration)/(Dietary Intake)
BCF =	Bioconcentration Factor (unitless); BCF = (Tissue Concentration)/(Media Concentration)
[a]	Surrogate chemical was used to obtain the BCF or BAF.
[b]	$BCFsl_i$ denotes BCFs for invertebrates. BCFs for earthworms were compiled from available literature sources (Beyer (1990) and Hendriks et al., 1995), and are footnoted accordingly. Factors reported in wet weight.
[c]	$BCFsl_v$ denotes BCF for vegetation. Unless otherwise noted, BCFs for vegetation for organic constituents were calculated using the Travis and Arms (1988) Log K_{ow} equation: Log BCFv = 1.588 - 0.578 Log K_{ow} and BCFs for inorganic constituents were obtained from Baes et al., 1984. Values for uptake into leafy material, stem, and straw were used. Values calculated in dry weight were converted to wet weight by assuming vegetation was 80% moisture (each value was multiplied by 0.2 to dilute BCF representative of hydration).
[d]	$BAFsl_m$ denotes BAF for mammals. Unless otherwise noted, BAFs for small mammals for organic constituents were calculated using the Travis and Arms (1988) Log K_{ow} equation: Log Biotransfer Factor mammal = -7.6 + Log K_{ow}. Biotransfer factors were converted to BAFs by multiplying by an average food ingestion rate (lactating and nonlactating animals) of 12 kg/day. BAFs for small mammals for inorganic constituents were estimated from biotransfer factors (BTFs) presented in Baes et al. (1984). BTFs were converted to BAFs by multiplying by an average food ingestion rate of 50 kg/day. BAF values were assumed to be wet weight.
[e]	Dioxin bioaccumulation for small mammals and invertabates were the general estimates regression models for TCDD presented in Sample et al. 1998a and Sample et al 1998b.
[f]	DDT and metabolite BCFs were estimated using Beyer (1990). A single BCF was calculated as the average of BCFs from the following sources: Beyer and Gish 1980; Davis 1971; Gish 1970; Wheatley and Hardman 1968; and Yadav et. al 1981 (obtained from Beyer 1990). Dry weight BCF was converted to wet weight BCF using a factor of 0.2.
[g]	Organochlorine BCFs were estimated using Beyer, 1990. BCFs from numerous studies were combined and an average BCF was calculated. References used were from the following sources: Beyer and Gish 1980; Davis 1971; Gish 1970; Jeffries and Davis 1968; Korschgen 1971; Venter and Reinecke 1985; Wheatley and Hardman 1968; and Yadav et. al 1981 (obtained from Beyer 1990) (DDT BCFs were included). Dry weight BCF was converted to wet weight BCF using a factor of 0.2.
[h]	Calculated using equation in USEPA (1999); log BCF = 0.819 x logKow - 1.146.
[i]	$BCFsl_i$ were estimated by using the Beyer (1990) BCF for '3,6-Dimethylphenanthrene as a surrogate for selected VOCs, SVOCs, PAHs, pesticides, and explosives. This BCF was selected because it is the greatest BCF presented in Table 25 of Beyer (1990).
[j]	$BCFsl_i$ were estimated using Beyer (1990) PAH specific results presented in Table 25. BCF = (Mean Tissue Concentration)/(Mean Soil Concentration)
[k]	$PCBsl_i$ for PCBs were calculated using Beyer (1990). BCFs from several studies were combined and an average BCF was calculated. References used were from the following sources: Diercxsens et. al. 1985; Kreis et. al. 1987; and Marquenie et. al. 1987 (obtained from Beyer 1990). Dry weight BCF was converted to wet weight BCF using a factor of 0.2.
[l]	$BCFsl_i$ for zinc used as a surrogate.
[m]	$BCFsl_i$ for cadmium was calculated using Beyer (1990) (reference number 41) and two values from Hendriks, et al., 1995 (see Table 1). Dry weight BCF was converted to wet weight BCF using a factor of 0.2.
[n]	$BCFsl_i$ for copper, manganese, nickel, and zinc are average values obtained from Hendriks et al., 1995 (see Table 1). Dry weight BCF was converted to wet weight BCF using a factor of 0.2.
[o]	$BCFsl_i$ for lead is an average of values obtained from Beyer (1990) and Hendriks et al., 1995 (see Table 1). Dry weight BCF was converted to wet weight BCF using a factor of 0.2.

Table A.2-24

Equations Used to Estimate Risk to Indicator Receptor Foodchain Models

New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Intake Assessment

Terrestrial Foodchain Model

$$\text{Intake (mg/kg - day)} = \left(\frac{\sum_1^f \left(C_{food} \times P_{food}\right) \times \left(\text{IR}_\text{F}\right) \times (\text{SFF}) \times (\text{EF})}{\text{BW}} \right)$$

Where:

C_{food} = Concentration of the constituent in the food (mg/kg)

P_{food} = Proportion of the diet comprised of the food item (unitless)

f = Number of different types of food (e.g., soil/sediment, invertebrates, vegetation (plants and fungi), mammals)

IR_F = Ingestion rate of food (kg/day)

SFF = Site foraging frequency (unitless)

EF = Exposure frequency (unitless)

BW = Body weight of the organism (kg)

Aquatic Foodchain Model

$$\text{Intake (mg/kg - day)} = \left(\frac{\left\{\left(\sum_1^f [C_{food} \times P_{food}] \times IR_f\right) + \left(C_w \times IR_w\right)\right\} \times (\text{SFF}) \times (\text{EF})}{\text{BW}} \right)$$

Where:

C_{food} = Concentration of the constituent in the food (mg/kg)

P_{food} = Proportion of the diet comprised of the food item (unitless)

f = Number of different types of food (e.g., soil/sediment, invertebrates, vegetation (plants and fungi), mammals)

IR_F = Ingestion rate of food (kg/day)

C_w = Concentration of the constituent in the surface water (mg/L)

IR_w = Ingestion rate of water (L/day)

SFF = Site foraging frequency (unitless)

EF = Exposure frequency (unitless)

BW = Body weight of the organism (kg)

$$C_{food} = C_{medium} \times BAF_{food}$$

C_{food} = Concentration in food – primary consumers (e.g., invertebrates, vegetation, mammal…etc)

C_{medium} = Concentration in medium (e.g., soil or sediment)

BAF_{food} = Bioaccumulation factor for food (primary consumer)

Table A.2-24
Equations Used to Estimate Risk to Indicator Receptor Foodchain Models
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Risk Calculations

Risk = Intake / RTV

$$RTV_{\text{Wildlife Species}} = TV_{\text{Test Species}} \times \left[\frac{BW_{\text{TestSpecies}}}{BW_{\text{WildlifeSpecies}}}\right]^{\frac{1}{4}}$$

Where:

$RTV_{\text{Wildlife Species}}$	=	NOAEL or LOAEL for the wildlife species
$TV_{\text{Test Species}}$	=	NOAEL or LOAEL for the laboratory test species (i.e., the toxicological benchmark)
$BW_{\text{Test Species}}$	=	Body weight of the laboratory test species
$BW_{\text{Wildlife Species}}$	=	Body weight of the wildlife species

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilograms.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.
[c] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in surface soil (0-2 foot depth interval).
[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.
[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).
[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or they were known laboratory contaminants (i.e. acetone).

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in combined surface and subsurface soil.

[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or they were known laboratory contaminants (i.e. acetone).

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Constituent of Potential Concern.
[b] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

ELCR	Excess lifetime cancer risk.
EPCsw	Exposure point concentration in surface water (mg/L).
HI	Hazard index (sum of the HQs).
HQ	Hazard quotient.
L/cm²/day	Liters per square centimeter per day.
L/m^3	Liters per cubic meter.
mg/L	Milligrams per liter.
NA	Not available.
VFsw	Volatilization factor for surface water.

Equations: (see Table A.2-13)

3.75 = Um = Mean annual wind speed (m/sec) for Roanoke, Virginia (USDOE 1986).

ELCRo = (EPCsw × 0.05 × 1 × 48 × 24 × CSFo) / (70 × 25,550)
ELCRd = (EPCsw × DA × 5,000 × 48 × 24 × CSFa) / (70 × 25,550)
ELCRi = (EPCsw × VFsw × 2 × 48 × 24 × CSFi) / (70 × 25,550)

HQo = (EPCsw × 0.05 × 1 × 48 × 24) / (70 × 8,760 × RfDo)
HQd = (EPCsw × DA × 5,000 × 48 × 24) / (70 × 8,760 × RfDa)
HQi = (EPCsw × VFsw × 2 × 48 × 24) / (70 × 8,760 × RfDi)

[a] Background levels for inorganics are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituent was considered at bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment quality Assessment, Status and Needs, February 2000.
[e] Constituents with a hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were metals present at concentrations below background (max • BKGD).

Table A.3.ERA-5
Baseline Level - Constituents of Potential Ecological Concern in Sediment
BUILDING DEBRIS DISPOSAL TRENCH
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

– =	Not available or applicable.
mg/kg =	Milligrams per kilogram.
NA =	Not available or applicable.
[a]	Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b]	See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c]	The refined hazard quotient (HQ) is the ratio of the EPC to the sediment screening level. HQs are rounded to one significant figure.
[d]	Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e]	Constituent was considered at bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment quality Assessment, Status and Needs, February 2000.

sum TU					0.455
Total TU [c]					1

Notes:
mg/kg Milligrams per kilogram.
PAH Polycyclic aromatic hydrocarbons.
TU Toxic unit.
TOC Total organic carbon.

TU = (concentration (mg/kg_{sed}) / TOC / FCV) x UF (2.75).
An uncertainty factor (UF) of 2.75 was used. TUs > 1 are in bold font.

[a] Final chronic value from USEPA (2003f).
Sediment Benchmarks for the Protection of Benthic Organisms: PAHs)
[b] Total organic carbon ranged between 2.2% to 5.4% at the site with an average TOC of 3.4%.
TOC here was assumed equal to the average site TOC.
[c] Sum of Toxic Units (TU) based on the Final Chronic Value, including an uncertainty factor of 2.75. Sediments containing less than or equal to 1 total TUs are acceptable for the protection of benthic organisms. If the total TU is greater than 1, sensitive benthic organisms may be unacceptably affected.

Notes:
– = Not available or applicable.
mg/L = Milligrams per liter.
NA = Not available or applicable.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The refined hazard quotient (HQ) is the ratio of the EPC to the surface water screening level. HQs are rounded to one significant figure.
[d] Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e] Constituent was considered at bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment quality Assessment, Status and Needs, February 2000.

Notes:

HQ = Hazard Quotient.
LOAEL = Lowest observed adverse effect level.
mg/kg = Milligrams per kilogram.
mg/kg-BW-day = Milligrams per kilogram of body weight per day.
NOAEL = No observed adverse effect level.

[a] Maximum concentration detected in surface soil (mg/kg).
[b] See Table A.2-20 for sources of soil bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-23 for sources of mammalian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Notes:

HQ = Hazard Quotient.
LOAEL = Lowest observed adverse effect level.
mg/kg = Milligrams per kilogram.
mg/kg-BW-day = Milligrams per kilogram of body weight per day.
NOAEL = No observed adverse effect level.

[a] Maximum concentration detected in surface soil (mg/kg).
[b] See Table A.2-20 for sources of soil bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-22 for sources of avian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Table A.3.ERA-14
Maximum Scenario Food Chain Modeling for the Great Blue Heron
BUILDING DEBRIS DISPOSAL TRENCH
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

– =	Not applicable.
HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
mg/L =	Milligrams per liter.
NA =	Not available.
NOAEL =	No observed adverse effect level.

[a] Maximum concentrations detected in surface water (mg/L) and sediment (mg/kg).
[b] See Table A.2-21 for sources of sediment bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-22 for sources of avian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Notes:

– =	Not applicable.
EPC =	Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration.
	EPCs marked with "m" are the maximum concentration.
LOAEL HQ =	Lowest observed adverse effect level hazard quotient.
mg/kg =	Milligrams per kilogram.
mg/L =	Milligrams per liter.
NOAEL HQ =	No observed adverse effect level hazard quotient.
[a]	Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b]	Foodchain modeling was conducted for bioaccumulative COPECs.

[a] Background levels for inorganics are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment quality Assessment, Status and Needs, February 2000.
[e] (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were inorganics present at concentrations below background (max • BKGD).

Table A.4.ERA-3
Screening Level - Constituents of Potential Ecological Concern in Surface Water
BAG LOADING AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

– = Not available or applicable.
mg/L = Milligrams per liter.
NA = Not available or applicable.

[a] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.

[b] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.

[c] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment quality Assessment, Status and Needs, February 2000.

[d] Constituents with a hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were inorganics present at concentrations below background (max • BKGD).

Notes:

HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
NOAEL =	No observed adverse effect level.

[a] Maximum concentration detected in surface soil (mg/kg).
[b] See Table A.2-20 for sources of soil bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-23 for sources of mammalian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
NA =	Not applicable.
NOAEL =	No observed adverse effect level.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.

[b] See Table A.2-20 for sources of soil bioaccumulation factors.

[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.

[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.

[e] See Table A.2-23 for sources of mammalian toxicity reference values.

[f] Refined hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Table A.4.ERA-10
Refined Scenario Food Chain Modeling for the American Robin
BAG LOADING AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
NA =	Not applicable.
NOAEL =	No observed adverse effect level.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.

[b] See Table A.2-20 for sources of soil bioaccumulation factors.

[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.

[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.

[e] See Table A.2-22 for sources of avian toxicity reference values.

[f] Refined hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Table A.4.ERA-13
Maximum Scenario Food Chain Modeling for the Great Blue Heron
BAG LOADING AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
mg/L =	Milligrams per liter.
NOAEL =	No observed adverse effect level.

[a] Maximum concentrations detected in surface water (mg/L) and sediment (mg/kg).
[b] See Table A.2-21 for sources of sediment bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-22 for sources of avian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Notes:

– = Not applicable.
COPEC = Constituent of Potential Ecological Concern.
EPC = Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
LOAEL HQ = Lowest observed adverse effect level hazard quotient.
mg/kg = Milligrams per kilogram.
NA = Not available.
NOAEL HQ = No observed adverse effect level hazard quotient.

[a] Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
R5: Region 5 Ecological Screening Levels (USEPA 2003e; R5).
EcoSSL: USEPA Ecological Soil Screening Levels (USEPA 2005b, EcoSSL).
Where readily available (i.e., EcoSSLs), the basis of the ESL is presented.
[c] Foodchain modeling was conducted for bioaccumulative COPECs.

Table A.4.ERA-16
Summary of Ecological Risk Characterization Results - Aquatic Habitat
BAG LOADING AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

– =	Not applicable.
EPC =	Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration.
	EPCs marked with "m" are the maximum concentration.
LOAEL HQ =	Lowest observed adverse effect level hazard quotient.
mg/kg =	Milligrams per kilogram.
mg/L =	Milligrams per liter.
NOAEL HQ =	No observed adverse effect level hazard quotient.
[a]	Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b]	Foodchain modeling was conducted for bioaccumulative COPECs.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilograms.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilograms.

PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

* = Surface soil
r = Rip-rap area

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilograms.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in surface soil.

[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or they were known laboratory contaminants (i.e. acetone).

Table A.4.HHRA-4
Selection Constituents of Potential Concern for Surface Water
BAG LOADING AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

CASN =	Chemical abstracts registry number.	NA =	Not available or not applicable.
COPC =	Constituent of Potential Concern.	RSL =	Regional Screening Level.
mg/L =	Milligrams per liter.	USEPA =	United States Environmental Protection Agency.

[a] Maximum concentration in surface water.

[b] The screening levels used were risk screening levels for tap water from USEPA (2008a). Screening levels based on non-cancer effects were adjusted by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.

c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit;

« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.

Some RSL values were based on surrogates as identified next to each value.

[c] Constituents detected with maximum concentrations greater than screening levels were considered COPCs unless they were essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Constituent of Potential Concern.
[b] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

Calculations of Blood Lead Concentrations (PbBs)
U.S. EPA Technical Review Workgroup for Lead, Adult Lead Committee
Version date 05/19/03

Table A.4.HHRA-17
Blood Lead Level Estimates for a Hypothetical Current Commercial/Industrial Worker Receptor
from Exposure to Surface Soil (0-1 feet below ground surface)
BAG LOADING AREA
Reasonable Maximum Exposure (RME) Scenario
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

1 Equation 1 does not apportion exposure between soil and dust ingestion (excludes WS, KSD).
When IRS = IRS+D and WS = 1.0, the equations yield the same PbBfetal,0.95.

***Equation 1, based on Eq. 1, 2 in USEPA (1996).**

PbB adult =	(PbS*BKSF*IRS+D*AFS,D*EFS/ATS.D) + PbB0
PbB fetal, 0.95 =	PbBadult * (GSDi1.645 * R)

****Equation 2, alternate approach based on Eq. 1, 2, and A-19 in USEPA (1996).**

PbB adult =	PbS*BKSF*([(IRS+D)*AFS*EFS*WS]+[KSD*(IRS+D)*(1-WS)*AFD*EFD])/365+PbB0
PbB fetal, 0.95 =	PbBadult * (GSDi1.645 * R)

Calculations of Blood Lead Concentrations (PbBs)
U.S. EPA Technical Review Workgroup for Lead, Adult Lead Committee
Version date 05/19/03

Table A.4.HHRA-18
Blood Lead Level Estimates for a Hypothetical Future Child and Adult Resident Receptor
from Exposure to Surface and Subsurface Soil
BAG LOADING AREA
Reasonable Maximum Exposure (RME) Scenario
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

1 Equation 1 does not apportion exposure between soil and dust ingestion (excludes WS, KSD).
When IRS = IRS+D and WS = 1.0, the equations yield the same PbBfetal,0.95.

***Equation 1, based on Eq. 1, 2 in USEPA (1996).**

PbB adult =	(PbS*BKSF*IRS+D*AFS,D*EFS/ATS.D) + PbB0
PbB fetal, 0.95 =	PbBadult * (GSDi1.645 * R)

****Equation 2, alternate approach based on Eq. 1, 2, and A-19 in USEPA (1996).**

PbB adult =	PbS*BKSF*([(IRS+D)*AFS*EFS*WS]+[KSD*(IRS+D)*(1-WS)*AFD*EFD])/365+PbB0
PbB fetal, 0.95 =	PbBadult * (GSDi1.645 * R)

Table A.5.Data-3
Soil Risk Assessment Dataset
Combined Surface and Subsurface Soil
IGNITER ASSEMBLY AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Constituent [a]	CASN	Frequency of Detection (FOD) [b]				Detects			Detection Limits			Maximum Location
		number of detects / number of samples			FOD %	Min - Max			Min - Max			
						(mg/kg)		(mg/kg)	(mg/kg)		(mg/kg)	
Vanadium	7440-62-2	137	-	139	99	10.8	-	98.4	–	-	–	50240
Zinc	7440-66-6	137	-	139	99	6	-	21800	–	-	–	SS-11

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in surface soil (0-2 foot depth interval).

[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or they were known laboratory contaminants (i.e. acetone).

Notes:
– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Constituent of Potential Concern.
[b] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

Receptor Population: Child Resident
Receptor Age: Child

[a] Minimum of the volatilization factor (identified with "V") and the particulate emission factor (PEF) (identified with "P"), both derived on Table A.2-11.

–	Not applicable.	HQ	Hazard quotient.	PEF	Particulate emission factor.
ELCR	Excess lifetime cancer risk.	m^3/kg	Cubic meters per kilogram.	VF	Volatilization factor.
EPCs	Exposure point concentration in soil (mg/kg).	mg/kg	Milligrams per kilogram.		
HI	Hazard index (sum of the HQs).	NA	Not available.		

Equations: (see Table A.2-11. Potentially mutagenic carcinogens (i.e., PAHs) adjusted to incorporate ADAFs of 4.6 for 2 years (ages 0 to 2) and 2.1 for 4 years (ages 2 to 6). Oral example: (EPC x 1 x 200 x 350 x CSF/(1,000,000 x 365 x 15)) x ((4.6 x 2/70) + (2.1 x 4/70)).

ELCRo = (EPCs × 1 × 200 × 350 × 6 × CSFo) / (1,000,000 × 15 × 25,550)
ELCRd = (EPCs × 2,800 × 0.2 × ABSd × 350 × 6 × CSFa) / (1,000,000 × 15 × 25,550)
ELCRi = (EPCs × 10 × 350 × 6 × CSFi) / ([VF or PEF] × 15 × 25,550)

HQo = (EPCs × 1 × 200 × 350 × 6) / (1,000,000 × 15 × 2,190 × RfDo)
HQd = (EPCs × 2,800 × 0.2 × ABSd × 350 × 6) / (1,000,000 × 15 × 2,190 × RfDa)
HQi = (EPCs × 10 × 350 × 6) / ([VF or PEF] × 15 × 2,190 × RfDi)

g/day =	Gram(s) per day.	ppm =	Part(s) per million.
GSDi =	Individual Geometric Standard Deviations.	µg/day =	Microgram(s) per day.
Het =	Heterogeneous population.	µg/dL =	Microgram(s) per deciliter.
Hom =	Homogeneous population.	µg/g =	Microgram(s) per gram.
PbB =	Blood lead.	yr =	Year.

USEPA Adult Lead Model (2003b) was used to assess exposure to lead.
Input values in bold font were receptor- and site-specific.

Table A.5.HHRA-16
Summary of Calculated Blood Lead Level Estimates
IGNITER ASSEMBLY AREA
Reasonable Maximum Exposure (RME) Scenario
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Exposure Medium/Receptor	Model Used [a]	Receptor Blood Lead Level[b]		Fetus Blood Level [b]
		Adult	Child	
		50th Percentile/ Geometric Mean (µg/dL)	range in seven years (µg/dL)	95th Percentile (µg/dL)
IGNITER ASSEMBLY AREA				
Surface Soil (0-1 feet below ground surface)				
Hypothetical Current Commercial/Industrial Worker Receptor	USEPA ALM	2.8	–	9.9
Surface and Subsurface Soil				
Hypothetical Construction Worker Receptor	USEPA ALM	2.8	–	9.9
Hypothetical Future Child Resident Receptor	IEUBK	–	4.4 - 8.2	–
Hypothetical Future Adult Resident Receptor	USEPA ALM	3.2	–	11

Notes:
– = Not applicable.
µg/dL = Microgram(s) per deciliter.

[a] USEPA ALM: USEPA Adult Lead Methodology Spreadsheet.
USEPA Technical Review Workgroup for Lead, Adult Lead Committee (USEPA, 2003b).
USEPA IEUBK: USEPA Integrated Exposure Uptake Biogenetic Model for Lead in Children (USEPA 2005).
[b] Compare to a target blood lead level of 10 mg/dL.

[a] Background levels for inorganics are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.
[e] Constituents with a hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were inorganics present at concentrations below background (max • BKGD).

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The refined hazard quotient (HQ) is the ratio of the EPC to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.

Table A.5.ERA-5
Maximum Scenario Food Chain Modeling for the Short-Tailed Shrew
IGNITER ASSEMBLY AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
NOAEL =	No observed adverse effect level.

[a] Maximum concentration detected in surface soil (mg/kg).
[b] See Table A.2-20 for sources of soil bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-23 for sources of mammalian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Table A.5.ERA-6
Refined Scenario Food Chain Modeling for the Short-Tailed Shrew
IGNITER ASSEMBLY AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
NOAEL =	No observed adverse effect level.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-20 for sources of soil bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-23 for sources of mammalian toxicity reference values.
[f] Refined hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Table A.5.ERA-7
Maximum Scenario Food Chain Modeling for the American Robin
IGNITER ASSEMBLY AREA
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
NOAEL =	No observed adverse effect level.

[a] Maximum concentration detected in surface soil (mg/kg).
[b] See Table A.2-20 for sources of soil bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-22 for sources of avian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Notes:

HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
NOAEL =	No observed adverse effect level.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.

[b] See Table A.2-20 for sources of soil bioaccumulation factors.

[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.

[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.

[e] See Table A.2-22 for sources of avian toxicity reference values.

[f] Refined hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:
– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.
[c] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

Notes:
– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/L = Milligrams per liter.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– =	Not detected/ not analyzed/ not applicable.	NA =	Not available or not applicable.
CASN =	Chemical abstracts registry number.	RSL =	Regional Screening Level.
COPC =	Constituent of Potential Concern.	USEPA =	United States Environmental Protection Agency.
mg/kg =	Milligrams per kilogram.		

[a] Maximum concentration in surface soil (0-2 foot depth interval).

[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in combined surface and subsurface soil.

[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Notes:

CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in sediment.

[b] The screening levels used were risk screening levels for the residential scenario from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit;
s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

mg/L = Milligrams per liter.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentration in surface water.

[b] The screening levels used were risk screening levels for tap water from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit;
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Constituents detected with maximum concentrations greater than screening levels were considered COPCs unless they were essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Notes:
– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Constituent of Potential Concern.
[b] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

– = Not available or applicable.
mg/kg = Milligrams per kilogram.
NA = Not available or applicable.

[a] Background levels for inorganics are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.
[e] Constituents with a hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were inorganics present at concentrations below background (max • BKGD).

[a] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[b] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the sediment screening level. HQs are rounded to one significant figure.
[c] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.
[d] Constituents with a hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT).

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The refined hazard quotient (HQ) is the ratio of the EPC to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.

Notes:

– = Not available or applicable.
mg/kg = Milligrams per kilogram.
NA = Not available or applicable.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The refined hazard quotient (HQ) is the ratio of the EPC to the sediment screening level. HQs are rounded to one significant figure.
[d] Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.

Total TU [c]					0.2			0.2			0.2			0.007

Notes:

mg/kg Milligrams per kilogram.
PAH Polycyclic aromatic hydrocarbons.
TU Toxic unit.
TOC Total organic carbon.

TU = (concentration (mg/kg_{sed}) / TOC / FCV) x UF (2.75).
An uncertainty factor (UF) of 2.75 was used. TUs > 1 are in bold font.

[a] Final Chronic Value, obtained from USEPA, 2003 (Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks for the Protection of Benthic Organisms: PAHs)
[b] Total organic carbon ranged between 2.2% to 5.4% at the site with an average TOC of 3.4%. TOC here was assumed equal to the average site TOC.
[c] Sum of Toxic Units (TU) based on the Final Chronic Value. Sediments containing less than or equal to 1 total TU s are acceptable for the protection of benthic organisms. If the total TU is greater than 1, sensitive benthic organisms may be unacceptably affected.

Notes:
– = Not available or applicable.
mg/L = Milligrams per liter.
NA = Not available or applicable.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.

[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.

[c] The refined hazard quotient (HQ) is the ratio of the EPC to the surface water screening level. HQs are rounded to one significant figure.

[d] Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.

[e] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.

Table A.6.ERA-8
Maximum Scenario Food Chain Modeling for the Short-Tailed Shrew
RAIL YARD
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
NOAEL =	No observed adverse effect level.

[a] Maximum concentration detected in surface soil (mg/kg).
[b] See Table A.2-20 for sources of soil bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-23 for sources of mammalian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
NOAEL =	No observed adverse effect level.

[a] Maximum concentration detected in surface soil (mg/kg).
[b] See Table A.2-20 for sources of soil bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-22 for sources of avian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Notes:

HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
NOAEL =	No observed adverse effect level.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.

[b] See Table A.2-20 for sources of soil bioaccumulation factors.

[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.

[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.

[e] See Table A.2-22 for sources of avian toxicity reference values.

[f] Refined hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Results of Refined Food Chain Models [c]

Notes:

– = Not applicable.
COPEC = Constituent of Potential Ecological Concern.
EPC = Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration.
EPCs marked with "m" are the maximum concentration.
LOAEL HQ = Lowest observed adverse effect level hazard quotient.
mg/kg = Milligrams per kilogram.
NA = Not available.
NOAEL HQ = No observed adverse effect level hazard quotient.

[a] Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
R5: Region 5 Ecological Screening Levels (USEPA 2003e; R5).
EcoSSL: USEPA Ecological Soil Screening Levels (USEPA 2005b, EcoSSL).
Where readily available (i.e., EcoSSLs), the basis of the ESL is presented.
[c] Foodchain modeling was conducted for bioaccumulative COPECs.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.

[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:
– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.

Vanadium	7440-62-2	9.94E+01	7.20E+02	n	5.50E+01	n		1.08E+02	no	**YES**	no
Zinc	7440-66-6	3.25E+03	3.10E+04	nm	2.30E+03	n		2.02E+02	no	**YES**	**YES**

Notes:

– =	Not detected/ not analyzed/ not applicable.	NA =	Not available or not applicable.
CASN =	Chemical abstracts registry number.	RSL =	Regional Screening Level.
COPC =	Constituent of Potential Concern.	USEPA =	United States Environmental Protection Agency.
mg/kg =	Milligrams per kilogram.		

[a] Maximum concentration in surface soil (0-2 foot depth interval).

[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n SL < 100X c SL; ** = where n SL < 10X c SL; n = noncancer; m = concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.

NA =
RSL =
USEPA =

[a] Maximum concentration in combined surface and subsurface soil.

[b] The screening levels used were from USEPA (2008a). Screening levels based on non-cancer effects were adjusted downward by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit; s = Concentration may exceed saturation concentration (Csat).
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Background levels for metals are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation, 2001).

[d] Constituents detected with maximum concentrations greater than adjusted residential screening levels were considered COPCs unless they were metals detected at concentrations lower than background, or are essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit;
« The screening level for lead is based on noncancer effects but uses a non-standard method and, therefore, is not adjusted by 0.1.
Some RSL values were based on surrogates as identified next to each value.

[c] Constituents detected with maximum concentrations greater than screening levels were considered COPCs unless they were essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Zinc	7440-66-6	1.35E+01	**YES**

Notes:
CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/kg = Milligrams per kilogram.
NA = Not available or not applicable.

[a] Maximum concentration in fish fillet.
[c] Constituents detected were considered COPCs unless they were essential nutrients (i.e., calcium, magnesium, potassium, sodium), or were known laboratory contaminants (i.e. acetone).

Notes:
– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/kg = Milligrams per kilogram.
mg/L = Milligrams per liter.

[a] Constituent of Potential Concern.
[b] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
Exposure to lead is evaluated by predicting resultant blood lead levels using the arithmetic average (avg).
The UCLs were calculated using ProUCL 4.0. The UCL used is the one recommended by ProUCL 4.0.

[a] The dermal absorption factor (DA) was calculated using Equation [0], [1], or [2], as indicated, from Table 2-13.

– Not applicable.
ELCR Excess lifetime cancer risk.
EPCsw Exposure point concentration in surface water.
HI Hazard index (sum of the HQs).
HQ Hazard quotient.
L/cm²/day Liters per square centimeter per day.
L/m^3 Liters per cubic meter.
mg/L Milligrams per liter.
NA Not available.
VFsw Volatilization factor for surface water.

Equations: (see Table A.2-13)

3.75 = Um = Mean annual wind speed (m/sec) for Roanoke, Virginia (USDOE 1986).

ELCRo = (EPCsw × 0.050 × 1 × 48 × 6 × CSFo) / (15 × 25,550)
ELCRd = (EPCsw × DA × 1,900 × 48 × 6 × CSFa) / (15 × 25,550)
ELCRi = (EPCsw × VFsw × 2 × 48 × 6 × CSFi) / (15 × 25,550)

HQo = (EPCsw × 0.050 × 1 × 48 × 6) / (15 × 2,190 × RfDo)
HQd = (EPCsw × DA × 1,900 × 48 × 6) / (15 × 2,190 × RfDa)
HQi = (EPCsw × VFsw × 2 × 48 × 6) / (15 × 2,190 × RfDi)

Calculations of Blood Lead Concentrations (PbBs)
U.S. EPA Technical Review Workgroup for Lead, Adult Lead Committee
Version date 05/19/03

Table A.7.HHRA-27
Blood Lead Level Estimates for a Hypothetical Current Commercial/Industrial Worker Receptor
from Exposure to Surface Soil (0-1 feet below ground surface)
WESTERN BURNING GROUND
Reasonable Maximum Exposure (RME) Scenario
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

1 Equation 1 does not apportion exposure between soil and dust ingestion (excludes WS, KSD).
When IRS = IRS+D and WS = 1.0, the equations yield the same PbBfetal,0.95.

***Equation 1, based on Eq. 1, 2 in USEPA (1996).**

PbB adult =	(PbS*BKSF*IRS+D*AFS,D*EFS/ATS.D) + PbB0
PbB fetal, 0.95 =	PbBadult * (GSDi1.645 * R)

****Equation 2, alternate approach based on Eq. 1, 2, and A-19 in USEPA (1996).**

PbB adult =	PbS*BKSF*([(IRS+D)*AFS*EFS*WS]+[KSD*(IRS+D)*(1-WS)*AFD*EFD])/365+PbB0
PbB fetal, 0.95 =	PbBadult * (GSDi1.645 * R)

NA = Not available or applicable.

[a] Background levels for inorganics are facility-wide soil background point estimates taken from Facility-Wide Background Study Report (IT Corporation 2001).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The maximum hazard quotient (HQ) is the ratio of the maximum constituent concentration to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.
[e] (COPECs) for screening level assessment unless they were essential nutrients and thus considered non-toxic (NT), or were inorganics present at concentrations below background (max • BKGD).
[f] Sum of individual dioxin/furan compounds multiplied by their individual TEFs.

Notes:
– = Not available or applicable.
mg/kg = Milligrams per kilogram.
NA = Not available or applicable.

[a] Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c] The refined hazard quotient (HQ) is the ratio of the EPC to the surface soil screening level. HQs are rounded to one significant figure.
[d] Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e] Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.

sum TU				0.001			0.238			0.208			0.104
Total TU [c]				0.004			0.7			0.6			0.3

Notes:
mg/kg Milligrams per kilogram.
PAH Polycyclic aromatic hydrocarbons.
TU Toxic unit.
TOC Total organic carbon.

TU = (concentration (mg/kg$_{sed}$) / TOC / FCV) x UF (2.75).
An uncertainty factor (UF) of 2.75 was used. TUs > 1 are in bold font.

[a] Final Chronic Value, obtained from USEPA, 2003 (Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks for the Protection of Benthic Organisms: PAHs)
[b] Where TOC was available for a sample, it was used in the calculation, otherwise, the average TOC at the site was used instead. Total organic carbon ranged between 2.2% to 5.4% at the site with an average TOC of 3.4%.
[c] Sum of Toxic Units (TU) based on the Final Chronic Value, including an uncertainty factor of 2.75. Sediments containing less than or equal to 1 total TU s are acceptable for the protection of benthic organisms. If the total TU is greater than 1, sensitive benthic organisms may be unacceptably affected.

Table A.7.ERA-7
Baseline Level - Constituents of Potential Ecological Concern in Surface Water
WESTERN BURNING GROUND
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Notes:

– =	Not available or applicable.
mg/L =	Milligrams per liter.
NA =	Not available or applicable.
[a]	Exposure point concentrations (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration. EPCs marked with "m" are the maximum concentration.
[b]	See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
[c]	The refined hazard quotient (HQ) is the ratio of the EPC to the surface water screening level. HQs are rounded to one significant figure.
[d]	Constituents with a refined hazard quotient (HQ) greater than 1 (HQ > 1), without a screening level (NSL), or bioaccumulative were considered constituents of potential ecological concern (COPECs) for baseline risk assessment.
[e]	Constituent was considered a bioaccumulative compound if listed on Table 4-2 of USEPA's Bioaccumulation Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status and Needs, February 2000.

Notes:
HQ = Hazard Quotient.
LOAEL = Lowest observed adverse effect level.
mg/kg = Milligrams per kilogram.
mg/kg-BW-day Milligrams per kilogram of body weight each day.
NOAEL = No observed adverse effect level.

[a] Maximum concentration detected in surface soil (mg/kg).
[b] See Table A.2-20 for sources of soil bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-23 for sources of mammalian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Notes:

HQ = Hazard Quotient.
LOAEL = Lowest observed adverse effect level.
mg/kg = Milligrams per kilogram.
mg/kg-BW-day = Milligrams per kilogram of body weight each day.
NA Not applicable.
NOAEL = No observed adverse effect level.

[a] Exposure point concentration (EPCs) are the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration.
EPCs marked with "m" are the maximum concentration.
[b] See Table A.2-20 for sources of soil bioaccumulation factors.
[c] Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-23 for sources of mammalian toxicity reference values.
[f] Refined hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Notes:

– =	Not applicable.
HQ =	Hazard Quotient.
LOAEL =	Lowest observed adverse effect level.
mg/kg =	Milligrams per kilogram.
mg/kg-BW-day =	Milligrams per kilogram of body weight per day.
mg/L =	Milligrams per liter.
NA =	Not available.
NOAEL =	No observed adverse effect level.

[a] Maximum concentrations detected in surface water (mg/L) and sediment (mg/kg).

[b] See Table A.2-21 for sources of sediment bioaccumulation factors.

[c] Measured whole body fish tissue concentrations were used where available (i.e., for inorganic); if constituent was not detected in whole body fish tissue, it was assumed equal to zero. Where constituents were not analyzed for in whole body fish tissue samples, tissue concentrations were estimated using the following formula:
Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.

[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.

[e] See Table A.2-23 for sources of mammalian toxicity reference values.

[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Notes:

– = Not applicable.
HQ = Hazard Quotient.
LOAEL = Lowest observed adverse effect level.
mg/kg = Milligrams per kilogram.
mg/kg-BW-day = Milligrams per kilogram of body weight per day.
mg/L = Milligrams per liter.
NA = Not available.
NOAEL = No observed adverse effect level.

[a] Maximum concentrations detected in surface water (mg/L) and sediment (mg/kg).
[b] See Table A.2-21 for sources of sediment bioaccumulation factors.
[c] Measured whole body fish tissue concentrations were used where available (i.e., for inorganic); if constituent was not detected in whole body fish tissue, it was assumed equal to zero.
Where constituents were not analyzed for in whole body fish tissue samples, tissue concentrations were estimated using the following formula:
Estimated tissue concentration = concentration in exposure medium x bioaccumulation factor.
[d] See Table A.2-24 for equations used to estimate dietary ingestion and Table A.2-19 for receptor exposure assumptions.
[e] See Table A.2-22 for sources of avian toxicity reference values.
[f] Maximum hazard quotient (HQ) = (estimated dietary ingestion)/(toxicity reference value). HQs are rounded to one significant figure.

Notes:
– = Not applicable.
COPEC = Constituent of Potential Ecological Concern.
EPC = Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration.
EPCs marked with "m" are the maximum concentration.
LOAEL HQ = Lowest observed adverse effect level hazard quotient.
mg/kg = Milligrams per kilogram.
NA = Not available.
NOAEL HQ = No observed adverse effect level hazard quotient.

[a] Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b] See Table A.2-18 for sources of ecological screening levels (ESLs); ESLs marked with 's' are based on a surrogate.
R5: Region 5 Ecological Screening Levels (USEPA 2003e; R5).
EcoSSL: USEPA Ecological Soil Screening Levels (USEPA 2005b, EcoSSL).
Where readily available (i.e., EcoSSLs), the basis of the ESL is presented.
[c] Foodchain modeling was conducted for bioaccumulative COPECs.

Notes:

– =	Not applicable.
EPC =	Exposure point concentrations - the minimum of the upper confidence limit (UCL) on the mean and the maximum concentration.
	EPCs marked with "m" are the maximum concentration.
FOD	Frequency of Detection.
LOAEL HQ =	Lowest observed adverse effect level hazard quotient.
mg/kg =	Milligrams per kilogram.
mg/L =	Milligrams per liter.
NOAEL HQ =	No observed adverse effect level hazard quotient.
[a]	Hazard quotients (HQs) greater than one are presented in bold font. HQs are rounded to one significant figure (unitless).
[b]	Foodchain modeling was conducted for bioaccumulative COPECs.

Notes:

– = Not detected/ not analyzed/ not applicable.
CASN = Chemical abstracts registry number.
mg/L = Milligrams per liter.
ND = Non-detects.
PAH = Polycyclic Aromatic Hydrocarbon.
USEPA = United States Environmental Protection Agency.
VOC = Volatile Organic Compound.

[a] Only chemicals detected at least once in all five areas are presented.
For duplicate samples, the highest detected value or the lowest detection limit were used.
For constituents analyzed in two methods, the result of the more precise method was used i.e., USEPA method 8260 over 8270 for VOCs, method 8270-SIM over method 8270 for PAHs, and method 8330 over method 8260 or 8270 for explosives.
[b] Frequency of detection (FOD) = number of detects / total number of samples analyzed.
[c] The exposure point concentration (EPC) was the upper confidence level on the mean (UCL) or the maximum concentration where the UCL was incalculable.
EPCs marked with "m" are based on the maximum detected concentration.
The UCLs were calculated using ProUCL 4.2. The UCL used is the one recommended by ProUCL 4.2.

Table A.8.HHRA-2
Selection of Constituents of Potential Concern for Groundwater
New River Unit, Radford Army Ammunition Plant, Radford, Virginia

Constituent	CASN	Maximum Concentrations [a]	Adjusted Tap Water Regional Screening Level (RSL) [b]			Is Constituent a Groundwater COPC? [c]

Notes:

CASN = Chemical abstracts registry number.
COPC = Constituent of Potential Concern.
mg/L = Milligrams per liter.
NA = Not available or not applicable.
RSL = Regional Screening Level.
USEPA = United States Environmental Protection Agency.

[a] Maximum concentrations in groundwater.

[b] The screening levels used were risk screening levels for tap water from USEPA (2008a). Screening levels based on non-cancer effects were adjusted by a factor of 10. For chemicals whose screening levels were based on cancer effects but the noncancer screening level was less than 10x the cancer level (tagged with c**), the non-cancer level was used after adjustment.
c = cancer; * = where: n RSL < 100X c RSL; ** = where n RSL < 10X c RSL; n = noncancer; m = Concentration may exceed ceiling limit;
Some RSL values were based on surrogates as identified next to each value.

[c] Constituents detected with maximum concentrations greater than screening levels were considered COPCs unless they were known laboratory contaminants or essential nutrients.

[d] Chromium (III) (Insoluble Salts) was used for the tap-water RSL value.

				Total ELCR		4E-05	100%	Total HI		0.4	100%

[a] The dermal absorption factor (DA) was calculated using Equation [0], [1], or [2], as indicated, from Table A.2-15.

– Not applicable.
ELCR Excess lifetime cancer risk.
EPCgw Exposure point concentration in groundwater (mg/L).
HI Hazard index (sum of the HQs).
HQ Hazard quotient.
L/cm²/day Liters per square centimeter per day.
mg/L Milligrams per liter.
NA Not available.

Equations: (see Table 2-15)

ELCRo = (EPCgw × 2 × 250 × 25 × CSFo) / (70 × 25,550)
ELCRd = (EPCgw × DA × 2,400 × 250 × 25 × CSFa) / (70 × 25,550)
HQo = (EPCgw × 2 × 250 × 25) / (70 × 9,125 × RfDo)
HQd = (EPCgw × DA × 2,400 × 250 × 25) / (70 × 9,125 × RfDa)

- Surface Water
- Paved Roads
- Drainage Ditch
- SWMU Area
- 1303 Building Footprint and Identification

Analytical Data Legend

J	Constituent concentration qualified as estimated
K	Estimated concentration bias high
L	Estimated concentration bias low
B	Constituent concentration quantified as estimated
3.4	Yellow shaded results indicate detection above Residential RSL
903	Green shaded results indicate detection above Industrial RSL
903	Bolded results indicate detection above Background (Inorganics only)
	Units for Soil and Sediment Samples reported in mg/kg (Miligrams per kilogram)
	Units for TCLP Samples reported in mg/L (Miligrams per Liter)

Note: Sample Locations SS-04, SS-04a, and SS-05 not located

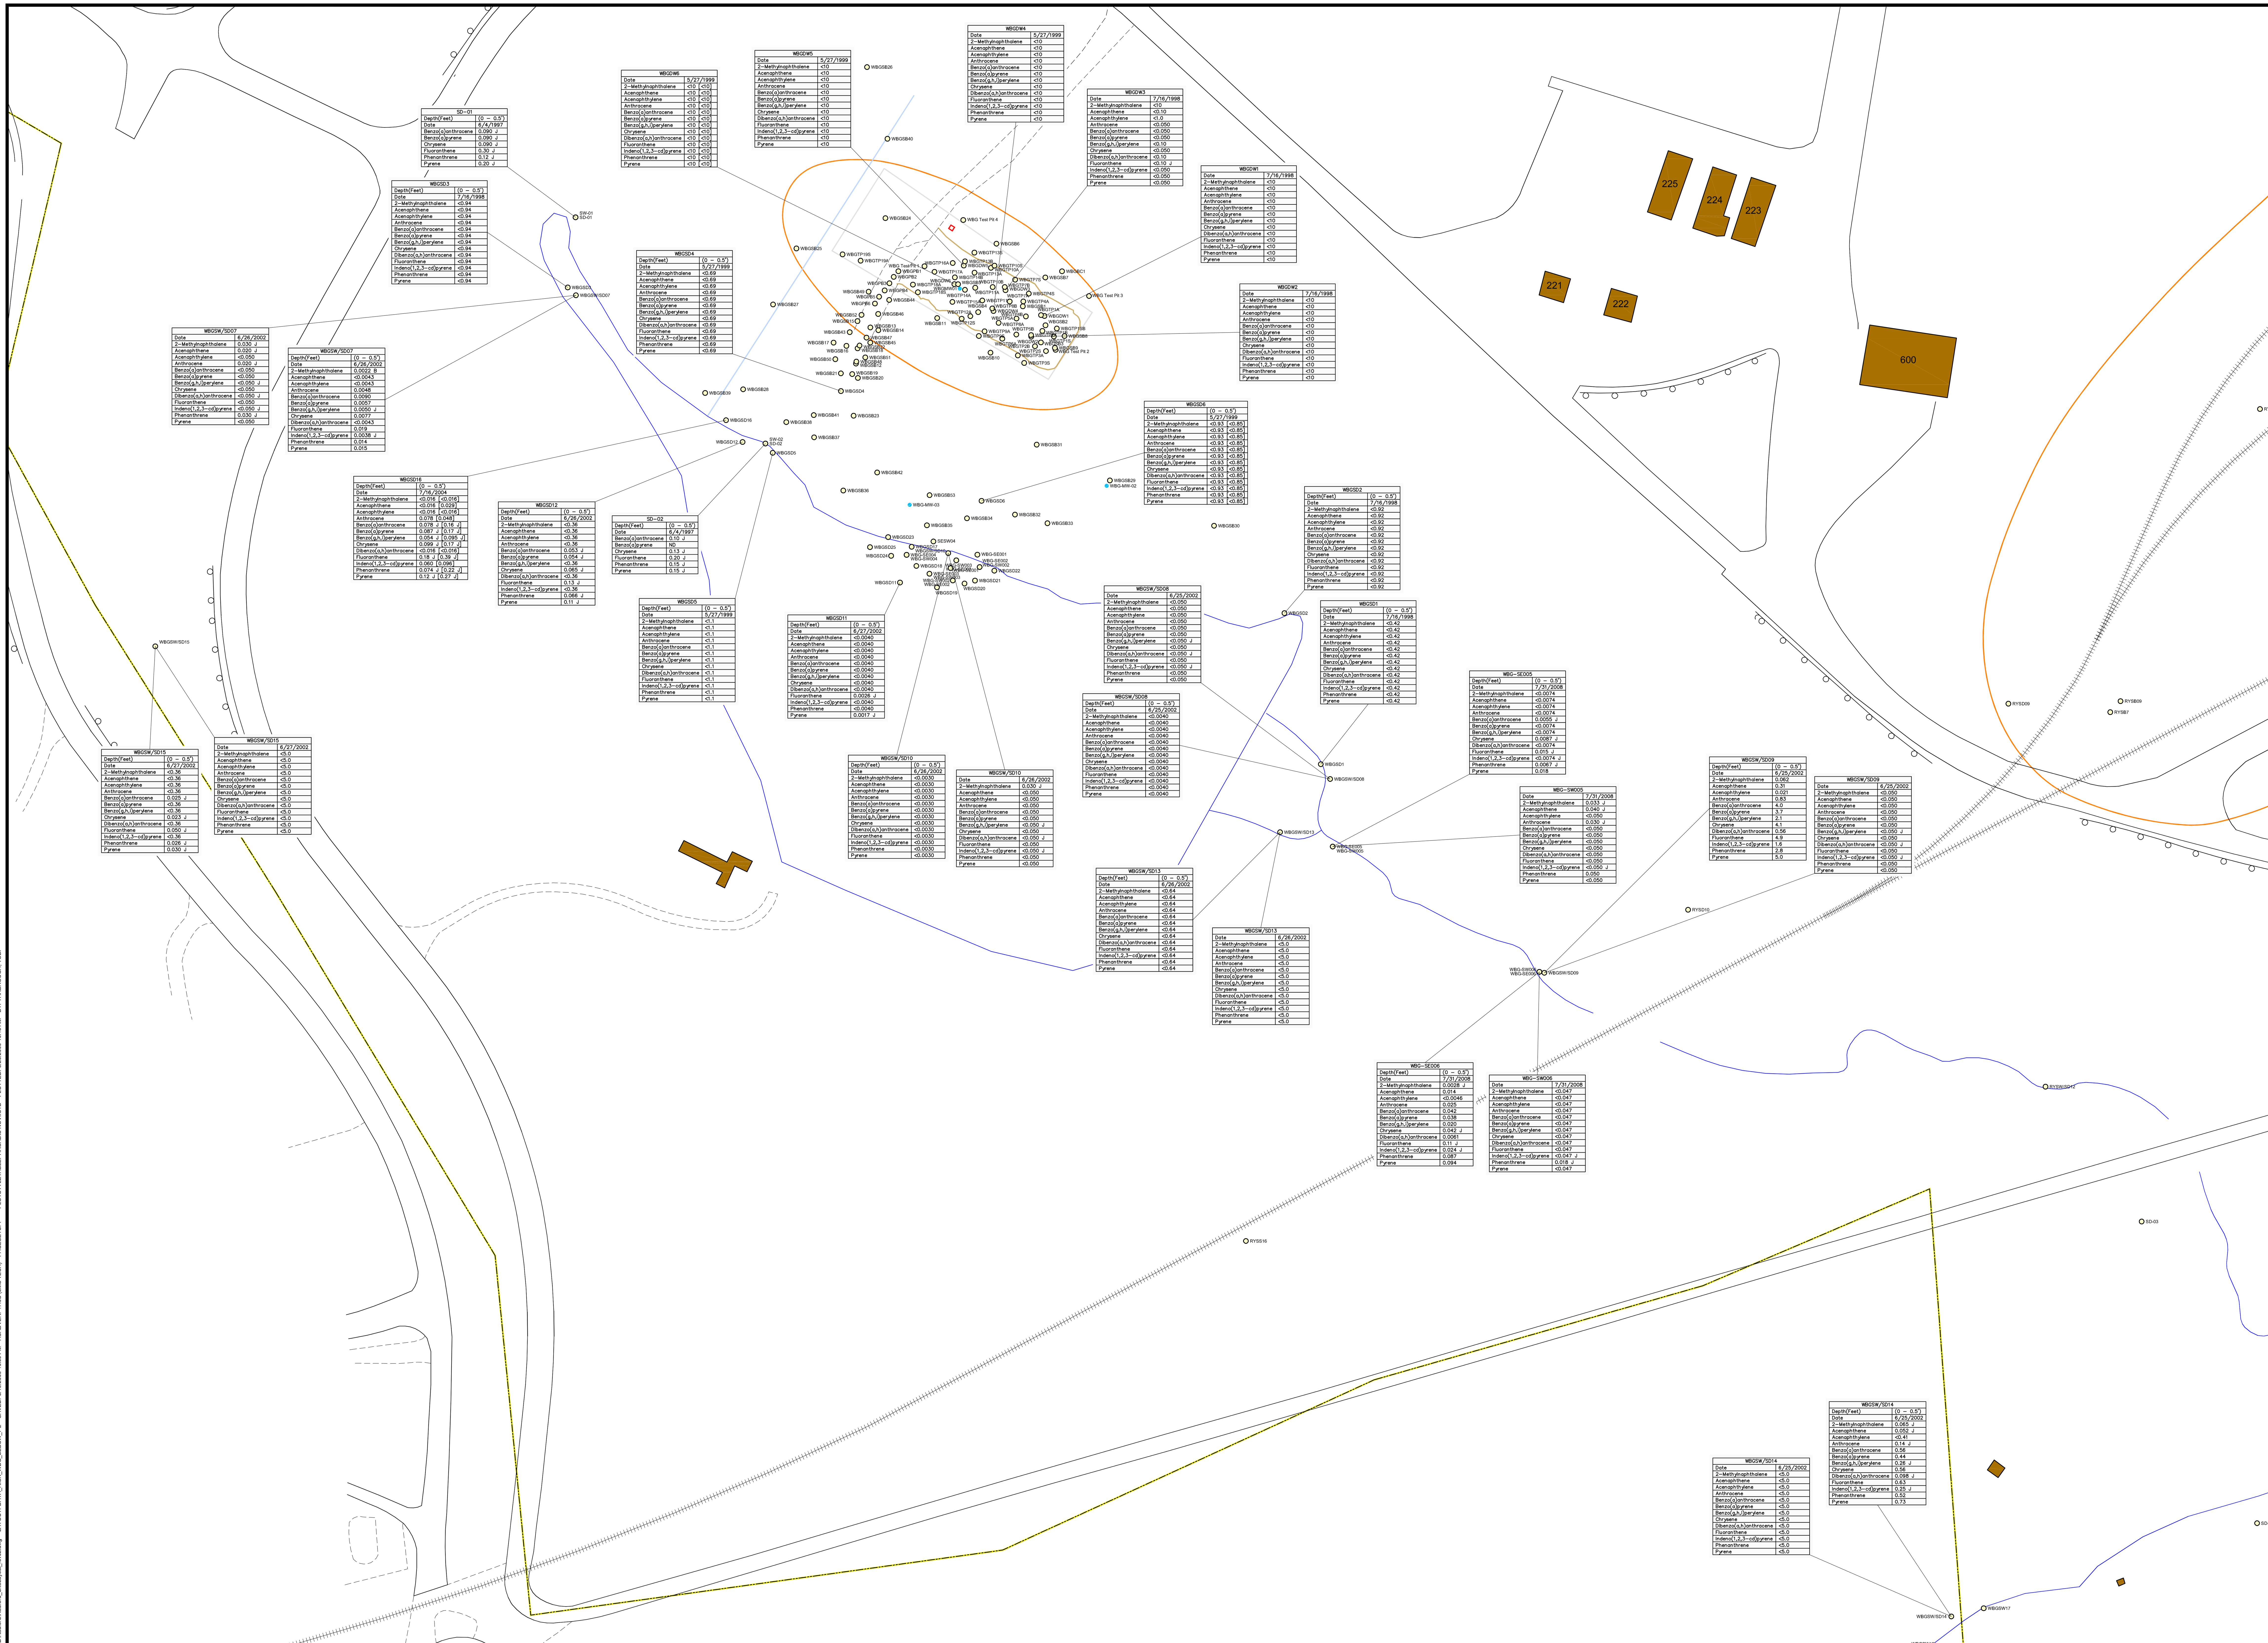
0 70 140
SCALE IN FEET

RADFORD ARMY AMMUNITION PLANT
RADFORD, VA

CONCENTRATIONS DETECTED IN SURFACE SOIL (0-1 FT BGS) INCLUDING: COPPER, LEAD, AND ZINC
WESTERN BURNING GROUND

ARCADIS

FIGURE
7-1

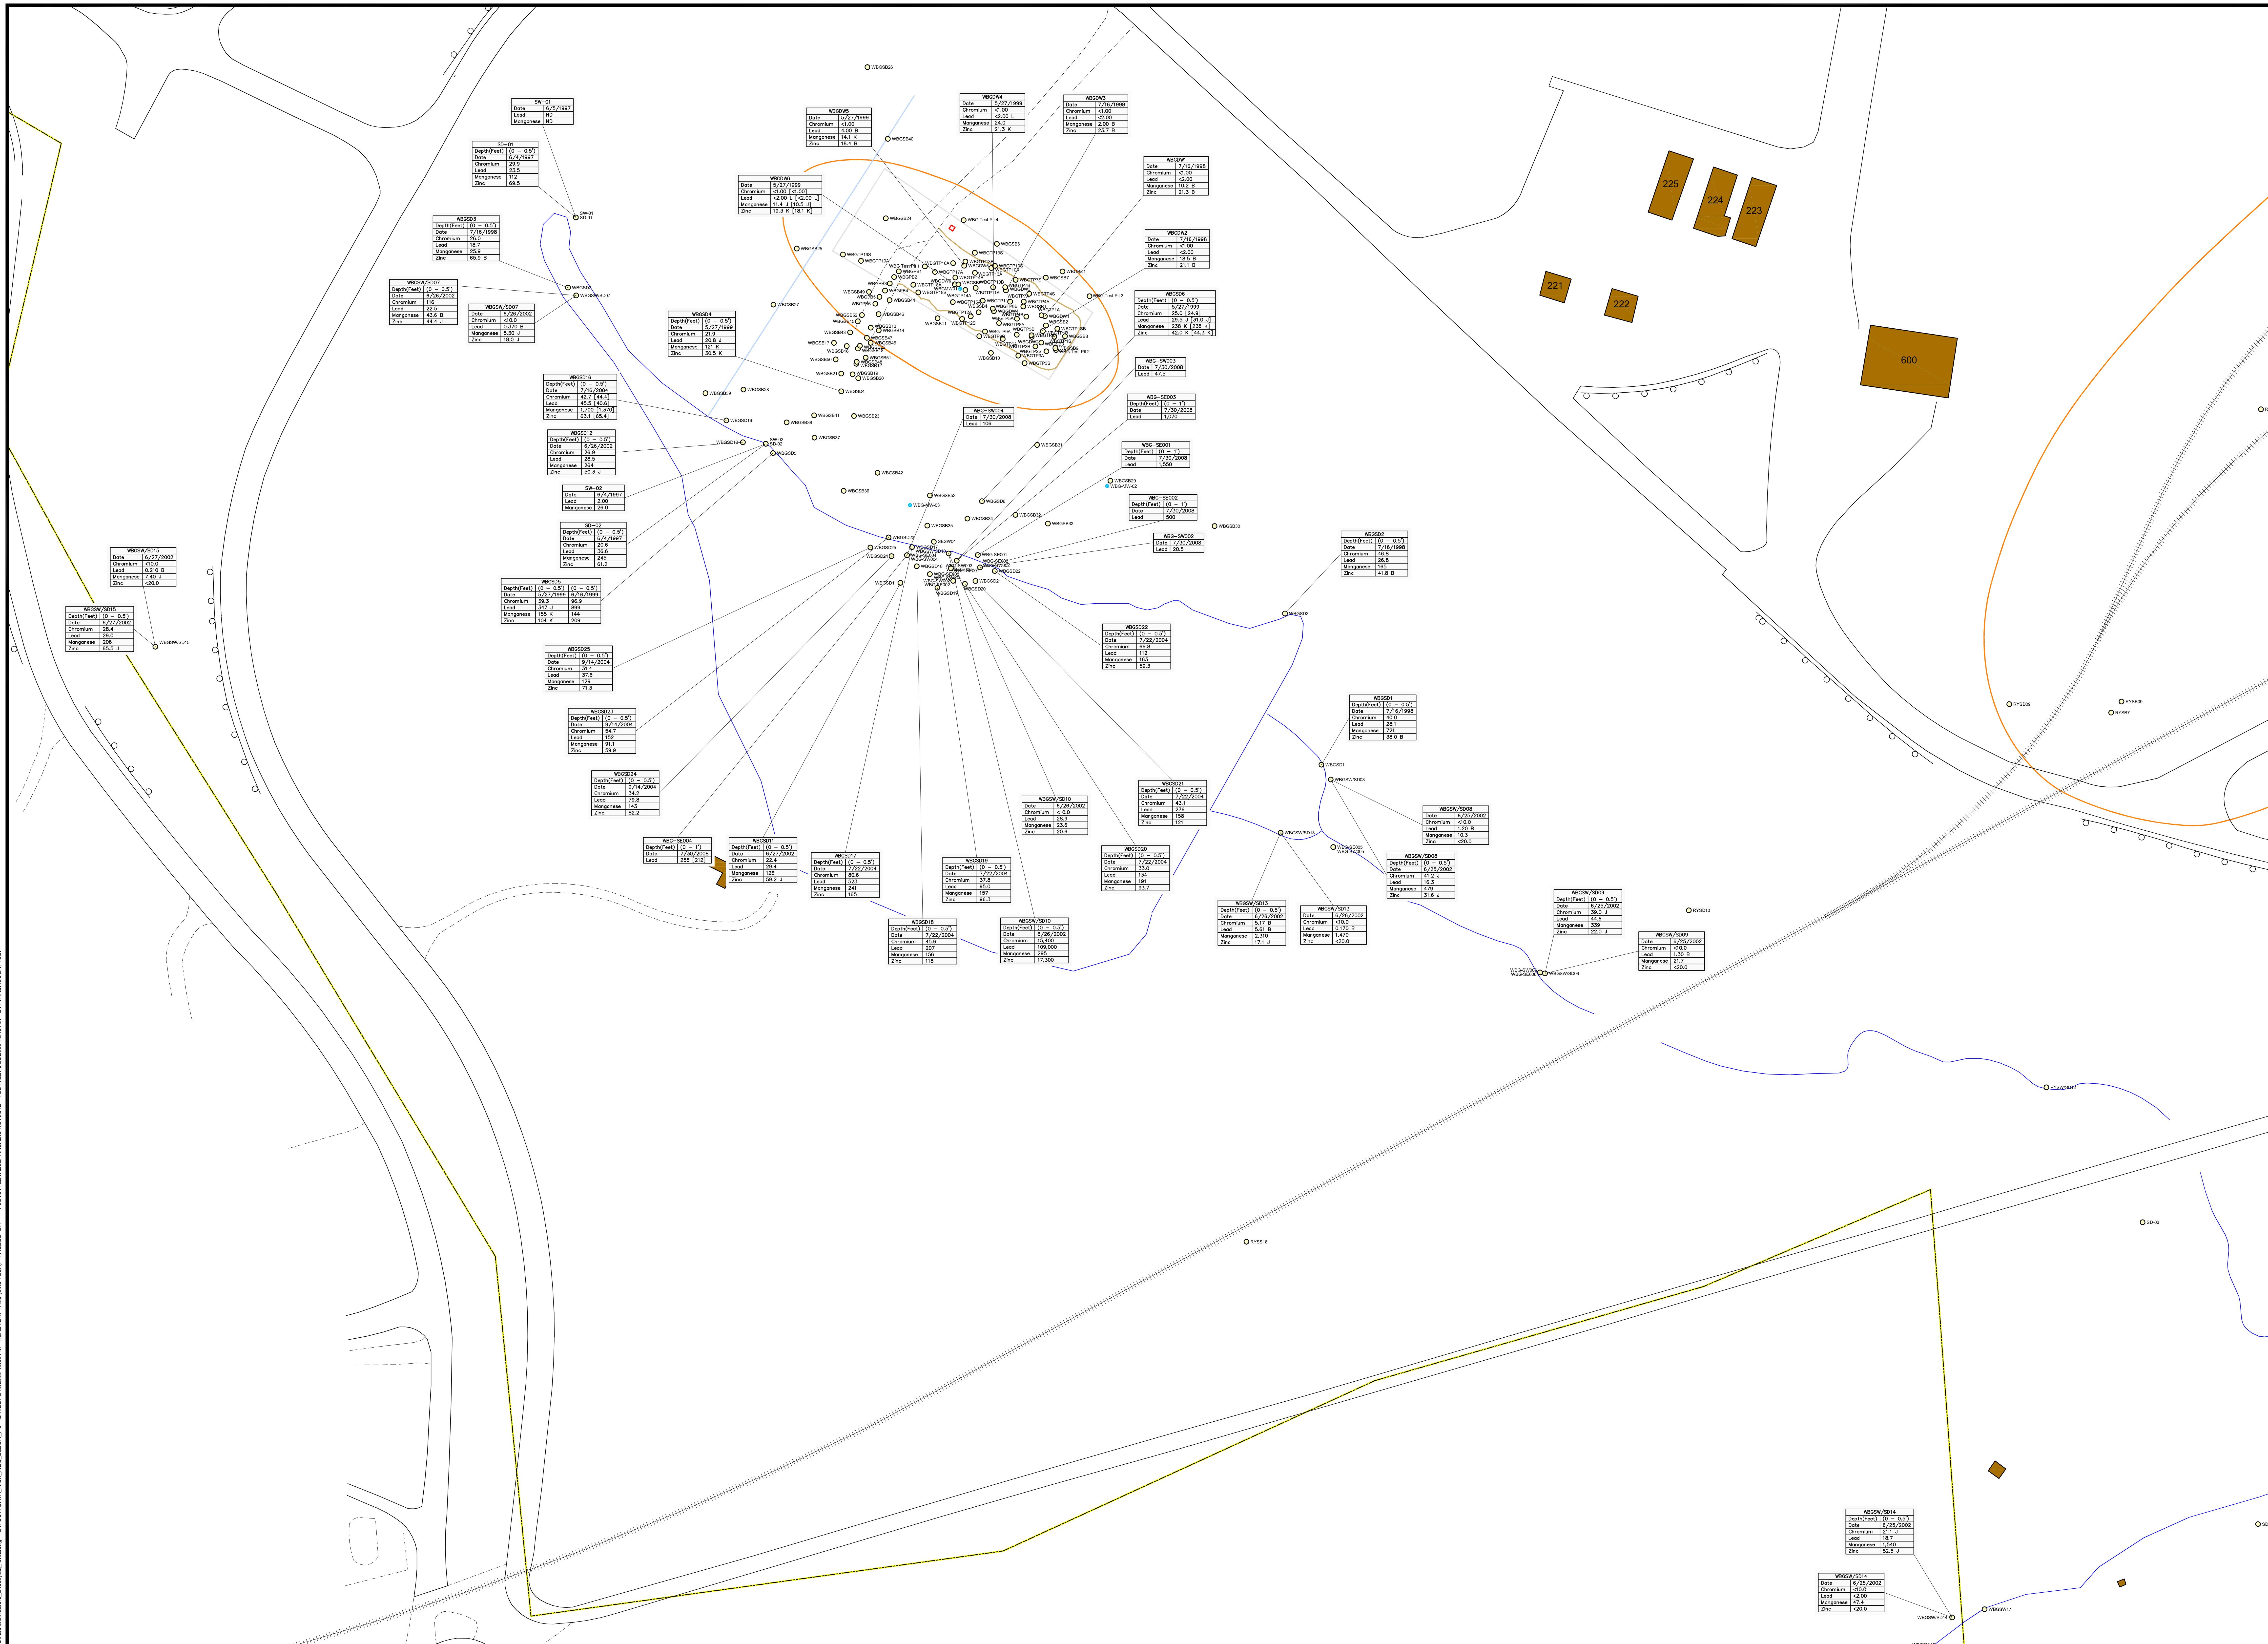


RADFORD ARMY AMMUNITION PLANT
RADFORD, VA

CONCENTRATIONS DETECTED IN SEDIMENT AND SURFACE WATER INCLUDING: POLYCYCLIC AROMATIC HYDROCARBONS WESTERN BURNING GROUND

ARCADIS

FIGURE 7-2



Legend

- Sample Location All Detects Below RSLs
- Sample Location Above Industrial Criteria and Background (Inorganics only)
- Sample Location Above Residential Criteria and Background (Inorganics only)
- Building Debris Disposal Trench
- Surface Water
- Paved Roads
- Drainage Ditch
- SWMU Area
- 1303 Building Footprint and Identification
